chemists, geographers, and soil scientists. Certainly, they are a very important legacy from the past societies from the Amazon.

Hodder, Ian (Modern World)

Ian Hodder
Anthropology Department, Stanford University, Stanford, CA, USA

Basic Biographical Information

Ian Hodder was trained at the Institute of Archaeology, University College London, and at Cambridge University where he obtained his Ph.D. in 1975. After a brief period teaching at Leeds, he returned to Cambridge where he taught until 1999. During that time, he became Professor of Archaeology and was elected a Fellow of the British Academy. In 1999, he moved to teach at Stanford University where he became Dunlevie Family Professor in the Department of Anthropology and where he was also for periods Director of the Stanford Archaeology Center. His first large-scale excavation project was at Haddenham in the east of England with Chris Evans; together they also set up the Cambridge Archaeological Unit. Since 1993, Hodder has reopened the excavations at Çatalhöyük in Turkey where he has led a large international team and has experimented with and developed reflexive methods.

Major Accomplishments

During the 1970s, Hodder developed techniques for spatial analysis in archaeology, drawing on quantitative and statistical techniques successfully developed in human geography (see Hodder and Orton 1976). His main application of these techniques was to the archaeology of Roman Britain. Unsatisfied with the ability of these techniques to discern the causes of cultural patterning, he then undertook several seasons of ethnoarchaeological fieldwork in Kenya, Zambia, and Sudan. The results of this work, published in 1982 (*Symbols in Action*; Hodder 1982a), demonstrated that material culture was actively used in social strategies and that it was meaningfully constituted. These ideas became part of a wider reaction against positivist processual archaeology that had initially taken hold in the United States in the 1960s and 1970s, strongly influenced by social evolutionary and adaptational accounts. A group of students at Cambridge in the late 1970s and early 1980s became more influenced by the social theoretical threads in anthropology and explored the critiques of positivism and the interpretive turn in anthropology. The first development of these ideas in archaeology was published in 1982 as the edited book *Symbolic and Structural Archaeology* (Hodder 1982b). Numerous other texts followed including Hodder's (1986) *Reading the Past* and books by Michael Shanks and Chris Tilley. The influences on this new approach were numerous, including critical theory, Marxism, structuralism, post-structuralism, and feminism, but also the agency and structuration theories of Bourdieu and Giddens. In 1985, Hodder termed this diversity of approaches postprocessual archaeology, and his main sustained attempt to apply the approach in prehistory was published in 1990 as *The Domestication of Europe* (Hodder 1990).

In the 1990s, the often-fierce debate between processual and postprocessual archaeology began slowly to settle down and the latter approaches often came to be termed interpretive. Hodder had by this time started excavating at Çatalhöyük, and he used this opportunity to develop a series of reflexive methods that made the field recording process more transparent and more open to diverging interpretation by multiple stakeholders. One idea was to bring forward interpretation to "the trowel's edge" instead of seeing excavation as descriptive followed by later interpretation in the laboratory or armchair. Another focus was to document the documentation process so that others could scrutinize the excavation and recording at a later date. But the main idea was to develop archaeology as a collaborative and participatory endeavor (Hodder 1999).

In the 2000s, Hodder became dissatisfied with the continuing tensions between positivist and rationalizing accounts and those informed by contemporary social theory. The rise in importance of material culture and materiality studies in archaeology had remained very much involved in social theory and insufficient attention had been paid to matter itself. Hodder developed a theory of entanglement that explored the dependencies between humans and things. Indebted to the theories of Bruno Latour, this approach was predominantly a response to the data from Çatalhöyük and to the necessity while working on that project of engaging with archaeologists with wide ranges of theoretical perspective. Entanglement theory was an attempt to bridge the divide between positivist and interpretive accounts of the past (Hodder 2012).

Throughout, Hodder's main concern has been to argue that archaeology is a social process. Its role in society is to create places and temporalities that others have to live by. Archaeology therefore has a duty to respond to the interests and needs of a diversity of communities and to take seriously the notion that it is as much about the present as about the past. In the 1990s and 2000s, he increasingly wrote about heritage and about the relationships between cultural heritage and human rights.

Dante Ange
Departmento de Antropología, Universidad de Tarapacá (UTA), Arica, Chile

Basic Biographical Information

Ian Richard Hodder (Fig. 1) is one of the most important figures in contemporary archaeological theory. He was born in Bristol, England, on November 23, 1948, and spent his childhood between Singapore and Oxford, where he attended Magdalen College School. He took his undergraduate degree at London University and pursued graduate and postgraduate studies graduate at Cambridge University. Hodder completed his Ph.D. and graduated with honors from Cambridge University in 1976, under the supervision of David Clarke.

Upon graduation, Hodder took a position as a Lecturer at Leeds University (1974–1977). Three years later, he returned to Cambridge as a Lecturer (1977–1990), Reader (1990–1996), and then Professor (1996). He has held numerous other appointments including adjunct positions at State University of New York at Binghamton (1984–1989) and the University of Minnesota, Minneapolis (1986–1994), and Visiting Professorships at the Van Giffen Institute for Pre- and Protohistory in Amsterdam (1980) and the University of Paris I-Sorbonne (1985). In 1999, he joined newly created department of ultural and

Hodder, Ian (Theory), Fig. 1 Ian Hodder

Social Anthropology at Stanford University, California. There, he was appointed as Dunlevie Family Professor, Chair of the Department, and Director of the Archaeology Center.

Hodder has conducted innovative archaeological and ethnographic work in England, Italy, Kenya, Sudan, and Turkey. In England, he directed the excavations at Wendens Ambo (1973–1974), Ledston (1976–1978), and Haddenham (1981–1990). He was codirector of excavations at Maxey (1980). He was the director of prehistoric site survey in Calabria, Southern Italy (1979–1980). Interspersed among his archaeological projects, he conducted ethnographic fieldwork in Kenya (1974–1976, 1980–1981, 1982–1983) and the Sudan (1978–1979). Hodder is best known, however, for his ongoing research project at Çatalhöyük, Turkey (1993–present).

Hodder has received numerous awards and honors. These include the Gordon Childe Prize from Institute of Archaeology, London (1971), the Oscar Montelius Medal from the Swedish Society of Antiquaries (1995), the Lucy Wharton Drexel Medal from the University of Pennsylvania Museum (2009), and the Huxley Memorial Medal from the Royal Anthropological Institute (2009). He has held Residential Fellowships at the Center for Advanced Study in the Behavioral Sciences at Stanford (1987) and the Research Center for Anatolian Civilization at Koç University (2010). He has received honorary doctorates from the University of Bristol (2009) and the University of Leiden (2011) and a national prize from Turkish Minister of Culture for scientific contributions to Turkish archaeology. He is a Fellow of the British Academy, the Royal Anthropological Institute, and the Society of Antiquaries.

Major Accomplishments

Hodder and his graduate students at Cambridge University provided an important critique of processual archaeology and offered new approaches to the study of the social past. Highly influenced by human geography, his initial contributions were related to spatial analysis of prehistoric settlements in England. His work *Spatial Analysis in Archaeology*, coauthored with Clive Orton (Hodder and Orton 1976), earned him recognition during the apogee of the processual archaeology. However, Hodder became dissatisfied with the rather sterile and one-dimensional view offered by this perspective and set in motion a strong critique of functionalist archaeology and systems theory (Hodder 1986; Hodder and Hutson 2003).

At this same time, Hodder was conducting ethnoarchaeological work that was to generate one of his most influential theoretical contributions to archaeology. Based on the study of the peoples of the Baringo district of the sub-Saharan Africa, Hodder sought to understand the processes of social boundary formation in diverse ethnic communities. At this time, most archaeologists were using ethnoarchaeology to secure Middle Range Theory. In his seminal contribution *Symbols in Action: Ethnoarchaeological Studies of Material Culture* (Hodder 1982a), he argued that material culture was meaningfully constituted and that it needed to be studied contextually because meaning is made of specific and non-

fixed relationships and associations. Thus, far from being a passive by-product or mere reflection of human behavior, material culture plays an active role in shaping social relationships, which, in turn, speak of identity, individual, and group intentionality. In 1982, Hodder also published *The Present Past* (1982c) in which he reflected on the use of ethnoarchaeology, as a means to contribute to an interpretation of the past.

Convinced of the need for a new agenda, Hodder and his students organized a series of seminars inviting other colleagues to present alternative theoretical perspectives to the New Archaeology. Although *Symbolic and Structural Archaeology* (1982b) is now considered among the most groundbreaking and influential books in archaeological theory, it did not achieve a felicitous reception at that time. The book was an attempt to overcome – despite the title – the constraining notions posed by structuralism and materialist determinism (Hodder 2007: 200). As part of this new current that was being developed, Hodder stressed the need to conceive material culture as a text that could be read and interpreted within a specific historical context. By the mid-1980s, Hodder had firmly stepped into the theoretical debate and ignited by the emergence of what came to be known as "Post-processual archaeology." In *Reading the Past* (1986), Hodder presented the first synthesis of the main theoretical trends of the newly born post-processualism.

During the second half of the 1980s, Hodder (1987a, b) also produced a series of edited volumes and papers that consolidated the "Post-processual" approach and its emphasis in the symbolic and active role of material culture as well as historicity and narrative. In both the importance of context was emphasized and – contrary to his detractors' accusations of relativism – he argued optimistically for making a more rigorous theoretical move to approach the past. In 1986, Hodder participated in the formation of what would become the World Archaeological Congress, alongside the late Peter Ucko and other colleagues. From then on his writings evidenced a rather politically engaged tone in his critiques to the neutrality of science, mainly influenced by the work feminist thinkers and postcolonial critique, that would later take shape through the notion of multivocality (Hodder 1999).

By the mid-1990s, he embarked upon his most important and ambitious project: the excavation of Çatalhöyük, a 9,000-year-old Neolithic site located in the Konya region in Turkey, which had been excavated in the 1960s by James Mellaart. Determined to provide an empirically based argument for his theoretical claims along with a post-processual methodology, he began a long-term project that starting in 1993 was envisioned to last for 25 years. Hodder was convinced that the site, because of its rich symbolic expressions and well-preserved condition of its architecture and artifacts, as reported by Mellaart, would provide enough data to test his ideas about the symbolic nature of the Neolithic revolution (Hodder 1990).

Over the years, the Çatalhöyük Project has involved up to nine excavation teams from various Turkish, Greek, US, and European universities, each comprised by specialists and graduate students who work in collaboration with the other teams, conducting their own research questions through diverse methods. In the course of the project, (Hodder 1999) fleshed out his reflexive methods through what he called "theorizing at the 'trowel's edge'" pointing out the importance of reflexivity, relationality, interactivity, and multivocality and the need to engage in a closer and more dialogical relationship between data and theory. Hodder embraced the Internet as a tool to promote the project and facilitate dialogue (http://www.catalhoyuk.com/). As part of this process, he began a critical inquiry into the field of ethics and the roles of tourism and heritage in the production of the past in the present.

Even though the debates between processualism and post-processualism have diminished, Ian Hodder continues to advance theory and practice. He has reengaged with an old interest: the symbolic aspects involved in the process of sedentarization, during the Neolithic (Hodder 2006). He has revamped his ideas about the role of the house as part of the process and attempted to move on from a previous structuralist framework, by emphasizing the role of ritual, ancestry, memory, and practice in a more pervasive fashion, and advanced his theory of material entanglement

(Hodder 2010, 2011). His most ambitious publication entitled *Entangled: An Archaeology of the Relationships Between Humans and Things* (2012), combines aspects of actor network theory with behavioral archaeology and evolutionary archaeology as a way of examining the dialectic of dependence and dependency between humans and things. Hodder's contributions to a series of seminal ideas and debates have undoubtedly changed archaeology.

H

Hokkaido Sequence and the Archaeology of the Ainu People

Hirofumi Kato
Center for Ainu and Indigenous Studies, Hokkaido University, Sapporo, Japan

Introduction

The archaeology in Hokkaido Island has long been recognized as a part of Japanese archaeology, or a northern variation of Japanese history

without attention to Hokkaido's particular history and the perspective of the Ainu. The primary focus of Japanese archaeology and history has been on state formation in the main island and narratives about the past have been constructed according to this framework. In other words, the archaeological narratives that have been produced present a model in which various local cultures are integrated under a homogenous cultural and political hegemony. The goal of those narratives was to support the unification of the nation state.

The greater part of history in Hokkaido Island was positioned outside of Japanese history. Long before Hokkaido and neighboring islands were annexed into Japanese territory, there were historical and cultural sequences of local societies, which gradually became related to the broader territory. Historical depictions of the Ainu, who did not have their own written history, have been created by the Japanese settlers, travelers, and bureaucrats, which consider the Ainu as peripheral undeveloped populations or resistant to the imperial state. However, accumulated archaeological information over the last decade suggests that the archaeological cultural sequence in Hokkaido Island and neighboring islands had an original complex historical dynamism. Now we must reconsider the normative framework and interpretations based on new perspectives, including the interpretation by the Ainu.

The recent shift in practice, evaluation, and interpretation around Northern Japan, especially in Hokkaido Island, addresses several exciting issues: the Ainu as the subject of the history, testing the validity of normative theoretical and methodological frameworks, repatriation of ancestral remains and grave goods, and ownership of historical cultural heritage. The challenge for contemporary archaeology in Hokkaido Island is developing relationships with all stakeholders in the local community, including the Ainu as indigenous peoples in Northern Japan (Fitzhugh and Dubreuil 1999; Tahara 2005, 2006, Walker 2006).

State of Knowledge

Hokkaido Island

Hokkaido Island (area: 83,453 km^2) is the second largest island of Japanese archipelago. The Tsugaru Strait separates Hokkaido Island from Honshu Island, and there is the Souya Strait between Hokkaido and Sakhalin (Karafuto) Islands. This island was formerly known as *Ezo*, *Yezo*, *Yeso*, and *Yesso* by written history, but the Ainu, who are indigenous peoples in Northern Japan, called this island as *Ainu-mosir* (the land where people live).

In 1869, when establishing the Development Commission after Meiji Restoration, the Meiji government decided to change the name of *Ezo-chi* (the land of Ezo). The Meiji government eventually decided to use the name *Hokkaido*. According to Takeshiro Matsuura, who is the nominator, this name of Hok-kai-do is including *Kai* element. The *Kai* element came from historical name of Ezo in the Sino-Japanese pronunciation. Even now, the element of Ainu culture is embedded in the cultural landscape as a place-name in Hokkaido such as rivers, mountains, and city name including Sapporo and has been continued to live as living culture.

Who Are the Ainu?

Ainu refers to indigenous peoples who originally inhabited the north part of the Japanese islands. Ethnographically and historically, the Ainu have been classified into three local populations: *Hokkaido*, *Sakhalin (Karahuto)*, and *Kuriles (Chishima) Ainu*. Besides that, the historical records support the Ainu lived in the northern part of Honshu island until the early twentieth century CE. They called as *Honshu Ainu*. Local populations include smaller local dialect groups.

In the early modern (Tokugawa shogunate) period, the Ainu has been positioned as an indigenous population in Northern Japan. After the modern state was established in Japan, the Meiji government forcibly incorporated the Ainu as a

part of the Japanese citizen and has carried out policies that are assimilated with the Japanese culture. To that end, Ainu's original culture tradition and the Ainu language have been threatened with extinction (Takakura 1960; Siddle 1996).

A living condition survey in 2013 estimated the Ainu population in 66 municipalities, Hokkaido to be just 16,786 people (23,782 people in 2006), but this number does not include Ainu populations around Tokyo and Osaka on the main island, Honshu.

Brief Colonial History in Hokkaido Island

The ancient Japanese state began to gradually encroach on the northern part of Honshu Island between the sixth and eighth centuries CE. Cultural contact between the ancestors of the Ainu and ancient Japanese started through active trading with each other.

In this trade between the ancient Ainu and the *Wajin* (the Honshu Japanese or the ethnic Japanese), bear and deer furs were mainly exported from the Ainu, and iron items, lacquerwares, and luxury goods such as rice, tea, and alcohol were brought in by the *Wajin*. Such economic exchanges have had a great influence for the Ainu's lifestyle (house structure, material culture, spiritual culture).

In the fourteenth century CE (the Muromachi period), the *Wajin* settlers constructed 12 political and trading posts (*Tate* in Japanese) in the southern part of Oshima peninsula, SW Hokkaido Island. As a result of the increase the *Wajin*'s population in Hokkaido Island, between the Ainu and the *Wajin* occurred armed conflicts. In 1457, the Ainu was led by chieftain *Koshamain* against the *Wajin* with an incident in which Ainu's youth was killed by blacksmith of the *Wajin* from the quarrel over the quality of an iron knife at Shinori village in SW Hokkaido. In this the Battle of Koshamain, 10 of 12 the *Wajin*'s posts had fallen by the Ainu. Eventually, the systematic resistance of the Ainu lasted nearly 100 years after the Battel of *Koshamain*.

In 1591, Yoshihiro Kakizaki attended Hideyoshi Toyotomi who was a chief advisor of the emperor and was granted the *Ezo-ga-shima* (which is now named Hokkaido Island). After that Yoshihiro Kakizaki became an independent load in this Island. In 1599, Yoshihiro Kakizaki became a vassal of Ieyasu Tokugawa and resented him the map of Ezo. In addition, Yoshihiro changed his surname from Kakizaki to Matsumae derived from the place-name which originally came from the Ainu's name *Matmae*.

Under the Tokugawa shogunate political system, the Matsumae clan had exclusive rights to trade with the Ainu and to guarantee. Relations between the Matsumae clan and the Ainu were sometimes hostile. Under the Matsumae clan control, there were numerous revolts by the Ainu. In 1669, the Battle of *Shakushain* took place. This systematic resistance by the Ainu spread throughout Hokkaido Island and continued until 1672. However, the systematic resistance by the Ainu finally ended the Battle of Menashi-Kunashiri in 1789. After the early nineteenth century CE, the whole of Hokkaido was controlled under the Tokugawa shogunate, and the Ainu gradually lost their original villages (*Kotan* in the Ainu) and traditional lifestyle.

In 1868, after the Meiji Restoration, Hokkaido was officially annexed by modern state of Japan. The beginning of the Meiji Restoration proved a turning point for the Ainu and their culture. The basis of the Ainu's policy by the Meiji government is assimilation; under this assimilation policy, the Ainu are prohibited for observing their daily customs. In 1871, The Hokkaido Development Commission (established in 1869) banned the tradition of burning house after death, male earing, and tattoos of women, also notified leaning Japanese. "The Land rules" and "the Land selling rules in Hokkaido" were established in 1872, and all of territory in Hokkaido Island was placed under the control of the Meiji government. In 1874, "Forest provisional rules" was established, and it was banned to cut trees for the traditional house and to correct bark of the tree for the material of the traditional clothes. "the Salmon and trout rules" in 1874 and "Hokkaido salmon and trout protection rules" in 1879 were notified, and

private salmon fishing was prohibited. Traditional deer hunting also was prohibited by "Hokkaido deer hunting rules" in 1876. In 1899, the Hokkaido Aborigine Protection Act was passed. The act primarily aimed to provide relief for the Ainu and help them become engaged in agriculture. However, this act designed the Ainu as "former aborigines" and clarified the distinction between the Honshu Japanese and the Ainu. This act was in force until 1997.

Chronological Sequence in Hokkaido Island

Compared with the main Island of Honshu, the archaeological cultural sequence in Hokkaido Island has many original aspects. Regarding the early stage of human occupation, the cultural traditions in Hokkaido and Honshu Islands have recognized commonalities. However, the later archaeological cultures in Hokkaido Island had strong uniqueness, which was different from cultural tradition in Honshu Island (Fig. 1).

The first inhabitants on Hokkaido Island date back to 35,000 years ago in the Upper Paleolithic period. Lithic complexes of Upper Paleolithic in Hokkaido had strong cultural influences from Siberian cultural traditions. The Upper Paleolithic complex is characterized by the technological diversity of microblade complexes. Siberian microblade traditions appeared first in Hokkaido, which were represented by wedge-shaped microcores and its reduction technologies (Izuho et al. 2012).

Under unstable climate conditions in the postglacial period, early Holocene complex hunter-gatherer society was sustainably continued on Hokkaido Island. These early Holocene hunter-gatherers are usually categorized as the northern Jomon culture. Still in this moment, the transition period between Upper Paleolithic and early Holocene culture cannot be seen as mass migration from Siberia to Hokkaido Island. Therefore, these Jomon culture's populations were the direct descendants of the Upper Paleolithic hunter-gatherer in Hokkaido Island.

Since Jomon culture, the prehistoric cultures in Hokkaido Island had remarkable originality of cultural tradition. Though a rice-cultivating culture (*Yayoi*) spread to Honshu Island in the sixth century BCE, their influence did not reach Hokkaido Island. Those living on Hokkaido Island maintained a hunter-gatherer society and formed various local cultures based on deer hunting, sea mammal hunting, and fishing. This post-Jomon culture stage is referred to as Epi-Jomon culture. The Epi-Jomon culture continued from the third century BCE to the seventh century CE. The Epi-Jomon culture had spread to the Tohoku region in northern part of Honshu Island and the southern part of Sakhalin Island from the fourth century to the sixth century CE. The diffusion of Epi-Jomon culture to Honshu Island and Sakhalin Island caused cultural integrations with neighboring archaeological cultural groups in the north and south and created new archaeological cultures. The Epi-Jomon culture that spread to Sakhalin Island had created northern marine hunter culture with an animal husbandry tradition called the Okhotsk culture under the influence of the ancient societies in the Lower Amur and Primorie region. On the other hand, the Epi-Jomon culture spread to the northern part of Honshu Island contacted with Kofun culture and subsequently created a complex hunter-gatherer culture that partly had a cultivation of millet.

After the fifth century CE, the Okhotsk culture dispersed to the Okhotsk seacoast from Sakhalin and Hokkaido Islands. After the tenth century CE, this archaeological culture had spread into Kuril Islands (Kikuchi 2004). This northern marine hunter culture had unique cultural characteristics that related to a bear cult and maintained trading networks with the lower Amur basin and Northern China. The middle stage (between the seventh and eighth century CE) of Okhotsk culture had strong influences from the *Mohe* culture from the lower Amur region. In addition, this culture had similar maritime adaptation technologies such as bone-antler tools with Tokarev culture (Lebedintsev 2004) and the Old Koryak culture (Vasil'evskij 1971) in the northern coast of Okhotsk sea. For the population of Okhotsk culture, previously scholars have been assumed them to be the *Mohe* populations in the Lower Amur basin. However, now it is better to recognize that the population of Okhotsk culture was cultural assemblage involving several regional populations in

Hokkaido Sequence and the Archaeology of the Ainu People, Fig. 1 Comparison between sequences of Hokkaido Island and Main island Honshu

H

the lower Amur region, Sakhalin Island, and the northern part of Hokkaido Island, not a single ethic group.

At the same period, in southwest Hokkaido, The Satsumon culture, which was closely related to ancient cultures on Honshu Island (i.e., strongly influenced by the Kofun and Nara culture), formed around seventh century CE (Yokoyama 1990). This culture was influenced from the south, especially in pottery-making traditions, mortuary systems, and the use of iron items as weapons and tools.

After tenth century, the Satsumon culture dispersed into northeast Hokkaido and integrated with the Okhotsk culture. Through this cultural integration, the historical Ainu culture was created in thirteenth century CE. Tradition of animal rituals in the Ainu culture such as whale worship and bear worship was passed on from the Okhotsk culture to the Ainu culture. On the other hand, cultural traditions such as iron items, woodcrafts, and millet farming were passed on from the Satsumon culture to the Ainu culture. In the thirteenth century, which was the transition period from the Satsumon culture to the Ainu culture, the pottery-making tradition disappeared, and the housing style also changed from pit-dwelling to flatland dwelling in Hokkaido Island.

As mentioned above, the historical sequence of Hokkaido Island is very different from Honshu and the southern Japanese islands. The history of Honshu Island has been presented as one evolving from hunter-gatherer societies, to agricultural societies, to early states. On the other hand, the historical sequence of Hokkaido has been continuous from sustainable hunter-gatherer societies to non-state ethnic formation. For this reason, we cannot sufficiently explain this historical dynamism in Hokkaido based on normative archaeological perspectives. Archaeological resources in Hokkaido are extremely unique and important for reconsideration of non-state societies. This long sequence of sustainable and open prehistoric hunter-gatherer culture suggests that we need new models and images to reconstruct the diversity of human history.

The Archaeology of the Ainu People

Archaeological culture between the thirteenth and the seventeenth century is called "Ainu culture period." This archaeological "Ainu culture" is characterized by iron pan, lacquerware, blue glass beads, accessories such as *tamasai* (a necklace) and *ninkari* (an earring), wooden pray stick, hunting equipment made by bone-antler, and *marek* (an iron salmon hook) (Udagawa 1980, 2001). During this period, iron swords, helmets, and armors can be seen, but these are imported from Honshu Island by trade. Also known as original ritual instruments for the Ainu culture are a wood-shaving stick, "inau," and a metallic hoe-shaped item, *bera-ushi-tomi-kamui* (Fig. 2). In Kuriyama town, there were found 12 hoe-shaped items together from a chache pit.

At the archaeological site, the *Kotan* as settlement, ritual ground, graves, shell-middens, and *chashi* have been excavated. The *Kotan* usually consists of two to five flatland-type dwelling called *chashi*. The *chashi* have regional variations, and building materials are different. In the southern Hokkaido Island, the *chise* called *ki-kitai-chise* was a thatched house. In central-internal area, the *chise* called *toprap-kitai-chise* is made by broad-leaf bamboo. But, in eastern Hokkaido Island the *chise* called *sarki-kitai-chise* is made by bark (Fig. 3).

Many of ritual grounds are related to the place of animal worship and shell-midden. In eastern Hokkaido Island, a ritual ground was found related with freshwater pearl mussel and ezo deer (Udagawa 1980), and in Rebun Island, northern Hokkaido Island, a ritual ground was found related with abalone shell and sea mammals (Fig. 4). The oldest bear worship remain *iomante* was found in Shiretoko-Shari in eastern Hokkaido Island and dates back to fifteen century CE (Kato et al. 2011).

The *chashi* is a special archaeological site that emerged after fifteenth century CE, and its origin has the place of ceremonies and the *chache* space of treasures and the lookout place. After sixteenth

(**a**) "Chosama" from *Ishuretsuzou*, Museum of Fine Art and Archaeology in Besancon; (**b**) *bera-ushi-tomi-kamui*, excavated from Kuriyama town; (**c**) *bera-ushi-tomi-kamui*, Tokyo National Museum

century CE, *chashi* was built as a fortress for defense. In Hokkaido Island are found 526 *chashies*. The chache are classified into the following four types: (a) type of an isolated island; (b) type of a hilltop; (c) type of a hill tip; (d) type of an edge of a cliff (Udagawa 2001).

Past Ainu Studies and Japanese Anthropology and Archaeology

One of the important issues in Japanese anthropology has been to understand the cultural identities and origins of the inhabitants of the Japanese archipelago. Around the end of the nineteenth and beginning of the twentieth century, when Western science was first introduced to Japanese anthropology, the Ainu people were repeatedly represented as the descendants of the Japanese Stone Age. Under this perspective, many of anthropologists and anatomists excavated Ainu human remains from Hokkaido, Sakhalin, and Kuril Islands between the 1880s and 1950s and discussed the formation process of inhabitants in Japanese archipelago.

In present studies, contact and hybrid models are becoming predominant for understanding the cultural formation processes of modern Japanese who integrated local populations with newcomers. The Ainu have been considered to derive from the Jomon. "The dual structure model" proposed by Hanihara Kazurou is the most popular model for the modern Japanese formation process (Hanihara 1991). Hanihara's model assumes that the local Jomon population migrated from Southeast Asia to the Japanese archipelago during the Upper Paleolithic period. There was then a second migration wave with rice cultivation and metal industries from Northeast Asia in the Yayoi period. Hanihara believed that modern Japanese

Hokkaido Sequence and the Archaeology of the Ainu People, Fig. 3 Regional differences of Ainu's house. (**a**): *ki-kitai-chise* was thatched house; (**b**) *toprap-kitai-chise* made by broad-leaf bamboo; (**c**) *sarki-kitai-chise* made by bark

Hokkaido Sequence and the Archaeology of the Ainu People, Fig. 4 Ritual ground related with abalone shell and sea mammals

populations gradually formed through this integration process, but this migration movement did not prevail on Hokkaido and Ryukyu islands. In these areas, which were less influenced by Yayoi culture migration, the Jomon population was ancestral to the Ainu.

Hanihara's model is based in outmoded ideas about cultural development and change. Recent aDNA studies also principally support this model (Kanzawa-Kiriyama et al. 2013; Adachi et al. 2017). In this context, newcomers who had more developed technologies and food production economies became the founders of early states, while hunter-gatherer populations who had a lower degree of contact with these innovations continued previous Stone Age traditions and food-gathering economies and eventually became the target of the ruler of the ancient and medieval state.

Until recently, anthropological and archaeological research interest in the Ainu has focused on their role in the formation of modern Japanese society. The term "Ainu archaeology" has appeared in the literature since 1945. This research largely considers the Ainu to be a culture that keeps some elements of Stone Age traditions (Komai 1952). Ainu people were considered the subject of the study, and researchers were interested in them as the descendants of the Stone Age in Japan or as living relics of the Jomon (Watanabe 1972). In this sense, past anthropological and archaeological Ainu studies never aimed to reveal the formation process and the cultural characteristics of the Ainu people.

Current Debates

Debates on the Meaning of "Ainu Culture"

There are, currently, two different meanings of the term "Ainu culture." One refers widely to the ethnic culture that has been historically developed by the living Ainu (Otsuka 1995; Irimoto 2014). The other is a narrowly fixed archaeological meaning dealing with explanations of the historical sequence of Hokkaido Island, indicating a period equivalent to medieval and modern ages for the thirteenth to eighteenth centuries in Honshu, the main island of Japan (Fujimoto 1984; Udagawa 2001).

In the broader sense, "Ainu culture" is found in northern areas of the Japanese archipelago, which includes Sakhalin Island and the northern Kuril Islands. Hitoshi Watanabe featured the bear-sending ceremony as an index of "Ainu culture" in social and religious practices and defined "Ainu culture" as "the cultural complex of bear sending ceremony" (Watanabe 1982; Fukazawa 1998; Amano 2003; Segawa 2005; Irimoto 2014). This "Ainu culture" is characterized by a worldview shaped by the idea of "Okuri" (sending of spirits), which is based on the reciprocity between the natural world (*Kamuy-moshiri:* the world of Gods) and the human world (*Ainu moshiri:* the world of Ainu). Their material culture, language, oral tradition, and dance are deeply related to this idea. By practicing and sharing this way of life, the identity of the Ainu has been maintained, and Ainu-pri (the way of life as an Ainu) has been reproduced.

"Ainu culture" was narrowly defined as an archaeological period and culture based on the emergence of new material culture, such as iron pots, lacquerwares, *ikupasuy* (stick for sending human words with alcohol), ceramic wares, and level ground houses and the disappearance of the ancient (Satsumon-type) pottery-making tradition. This usage of "Ainu culture" is problematic. Using the name of the living ethnic group as a label for a particular historical cultural stage is inappropriate. There is no evidence of displacement by the pre-stage "Satsumon culture" by the archaeological "Ainu culture."

Furthermore, recent genetic studies suggest that there was not much biological contact between local populations in Hokkaido and the Jomon on Honshu (Adachi et al. 2009, 2011). It has been pointed out that the unique ethnic formation processes in Hokkaido have hereditary influences of the groups in northeast Eurasia (Sato et al. 2009). In other words, the cultural shift from Satsumon culture to the archaeological "Ainu culture" occurred within the same ethnic group, and it is a tautology to discuss the "formation of Ainu culture" only by the appearance of

materials related to the "Ainu culture" after the eighteenth century (Watanabe 1972).

In addressing the question of what "Ainu culture" is, a central problem we face is that when we define the ethnic culture as stationary, we are blind to its variability. Ainu cultural history has been treated as a broadly conceived ethnic unit and narrowly defined archaeological culture and has been the object of comparative studies and the regional case studies in Japanese history and Japanese archaeology. Today, it is necessary to understand these dual usages.

The Impact of Ancient DNA Studies

Recent genetic studies have drawn considerable attention. The study of ancient DNA from Jomon sites has been used to reconsider population homogeneity of the early settlers of the Japanese archipelago. Traditionally, inhabitants of the Japanese archipelago during the Jomon period were considered to be a homogeneous human group: the "Jomon population." However, ancient DNA analysis based on Jomon skeletal remains from archaeological sites has shown local diversity in the structure of mtDNA haplogroups between Hokkaido and Honshu islands (the Tokyo Bay area) (Adachi et al. 2009, 2011). The Hokkaido Jomons were biologically isolated from other populations for a prolonged period. The frequency of mtDNA haplogroups from Hokkaido Jomons suggests genetic similarities with modern Ainu and indigenous peoples from the lower Amur region. The most distinctive feature of the haplogroup structure of the Hokkaido Jomons is the high frequency of haplogroup N9b, with a common ancestor calculated to be c. 22,000 years. It is likely that human migration to Hokkaido from Siberia occurred before the Jomon (Adachi et al. 2011).

In another study, the diffusion of other haplogroups from Siberia has occurred after the Jomon period in Hokkaido (Sato et al. 2009). The haplogroup Y was not present in the Hokkaido Jomon sample (Adachi et al. 2011) but was found to be the most dominant haplogroup in the lower Amur region. This haplogroup is the most prevalent in the Ainu today (Adachi et al. 2017). Genetic testing of ancient DNA from skeletal material from Okhotsk culture sites dating to the fifth to tenth century CE indicates that haplogroup Y was common in the Okhotsk people. In fact, the dispersal of Okhotsk culture from the lower Amur to Hokkaido might reflect an increase in the number of people with a haplogroup Y-dominated mtDNA profile in Siberia. Based on this data, the haplogroup Y may have been introduced to the Ainu by the Okhotsk people after fifth century CE.

These genetic studies force us to reconsider the historical formation processes of the Ainu (Adachi et al. 2017). While previous explanations posited that historical Ainu culture originated in a merger of the Okhotsk culture with the Satsumon culture, the genetic evidence indicates that the impact from the north may have been more significant. In further studies, it is necessary that we focus more on regional characteristics of the Hokkaido Jomon and reexamine a simple framework for Jomon culture. There is a need to study more deeply the population and cultural influences from Okhotsk culture in the formation process of Ainu culture and to review of the cultural and subsistent aspects of Ainu culture and its regional diversities.

Recent DNA study has remarkable progress. However, while such innovative research is processing, there is a criticism that sufficient explanation is lacking about how to sample the data for research, obtain informed consent during the sampling process, and share the research results to the Ainu communities. Researchers assert that research was conducted with permission from the relevant indigenous organization. However, there are diverse opinions on indigenous people's side, and it is difficult to prove heard opinions widely. DNA should involve extremely high personal information, and when considering the social impact of research results, it is necessary to reconsider whether the procedure by the previous researcher was sufficient or not enough.

The Nibutani Dam Controversy and Indigenous Heritage

Archaeological sites excavated by archaeological research include ancestral settlements and memories that were lost in present time. Through these investigations, local histories are reconfirmed, and cultural identity has often newly emerged inside the local community. In this context, archaeological site is part of an important indigenous cultural heritage and can be recognized as a living heritage for indigenous community members (Smith and Wobst 2005; Watkins 2000). It has been pointed out that indigenous heritage belong to indigenous peoples; however, it is not always clear that their attribution has not been legally stipulated.

In Japan, archaeological sites are protected by Act on Protection of Cultural Properties, but this legislation is not stated on the identity or ownership of the Ainu cultural property. When regarding the relationship between indigenous right of cultural heritage for the Ainu and archaeology, the judgment of the Sapporo District Court in 1997 can be highly appreciated as a landmark decision (Levin 1999, 2001). By this judgment, Ainu policy in Japan drastically changed from assimilation to cultural protection.

The Nibutani area in Biratori town is the area with the largest population of its residents being the Ainu in all of Hokkaido. The construction area for the Nibutani Dam included the place of ceremonies such as *Chipusanke* and the sacred site such as *Chinomishir*. It was an important place for the tradition of the Ainu culture. The *Chipsanke* was originally a ceremony handed down by the Ainu to set afloat newly built wooden canoe. This is practiced until around 1948 (Fig. 5).

The project plan started in 1973. Since it was confirmed that archaeological sites existed inside of construction area, the requested archaeological excavation was conducted from 1983 to 1985, and the remains of old *kotan* (village) with two graves before seventeenth century CE and two chashi was found in the project planned area (Fig. 6).

After this, the two Ainu elders who were part of landowners, Mr. Tadashi Kaizawa and Mr. Shigeru Kayano, refused to sell their land to the government. In 1987, the Ministry of Construction decided to take their land according to the Land Expropriation Law. Mr. Kaizawa and Mr. Kayano made a request for an examination of the Confiscatory Administrative Rulings to the Ministry of Construction. However, the Ministry of Construction rejected their request for the examination. As the result, Mr. Kaizawa and Mr. Kayano decided to raise an administrative lawsuit in the Sapporo District Court seeing an injunction against the Nibutani Dam Construction Project.

In 1997, the Sapporo District Court handed down a landmark decision. The ruling rejected the injunction on the dam construction. However, at the same time, the ruling pointed out that the government failed to give consideration to the uniqueness of the Ainu culture and did not consider the negative impacts of dam construction on the Ainu and their culture. The judgment also pointed out the detailed losing interest and cost for the Ainu by the dam construction: (1) the minority status of Nibutani area residents, (2) cultural characteristics of the Ainu people, and (3) Ainu culture in the Nibutani area. On losing interest Ainu culture in the Nibutani area involved the ceremonial place for the *Chipusanke*, the *Chashi* as archaeological site, and *Chinomishiri* as sacred site. The important part of this judgment, chief judge Mr. Kazuo Ichimita stated that "comprehensivery viewing the above recognized facts, we can see that for the most part of the Ainu people habe inhavited Hokkaido from before the extension of our country's rule. The formed thier own culture and had identity. . .Accordingly, the definition provided above of an "indigenous people" should certaily apply."(Levin 1999: 32). This ruling is the first judgment by Japanese court recognizing that the Ainu are indigenous people.

In response to this decision, the government did not appeal, and the ruling was finalized. In 1997, the Hokkaido Former Aborigines Protection Act was abolished, and Act on Promotion of the Ainu Culture was enacted.

Repatriation of Ainu Ancestral Human Remains

According to survey in April 2017 conducted by the Ministry of Education, Culture, Sports, Science and Technology, Japan (MEXT), currently 1676 individuals of the Ainu ancestral human remains are stored in 12 universities in Japan. Also 76 individuals of Ainu human remains are stored in 12 museums in Japan. These remains were collected by anatomists and anthropologists for the purpose of racial anthropological research since the late nineteenth century CE. The excavation for the anthropological collections by anthropologists continued until the 1970s. The largest collection is stored at Hokkaido University. 1015 remains are stored in this moment. There are also 201 human remains at the University of Tokyo and 87 remains at Kyoto University. In Sapporo Medical College has also been stored 294 remains, but this collection includes archaeologically excavated Ainu ancestral human remains that were registered as cultural property.

The request of repatriation on ancestral human remains from Ainu communities started in the 1980s. At the beginning, Department of Medicine, Hokkaido University, recognized Ainu ancestral remains as academic collection for research and disagreed to repatriate to Ainu communities (Hokkaido University 2013). However, in response to the request from the Hokkaido Utari Association (present Hokkaido Ainu Association), they agreed part of collections to repatriate to communities from 1982. Between 1982 and 2001, Hokkaido University repatriated 35 human remains to local communities, in response from 5 local Ainu organizations.

In July 2009, the Advisory Council for Future Ainu Policy under the Chief Cabinet Secretary submitted a report for the future Ainu policy. In this report, it was proposed to establish the memorial facility for the Ainu ancestral remains that have been stored in universities and museums. However, in September 2012, some Ainu elders who opposed this decision have filed a suit for the repatriation with the Sapporo District Court. Meanwhile, in April 2015, Hokkaido University established the repatriation office for Ainu human remains. After July 2016, the Sapporo District Court presented a settlement proposal with plaintiffs and Hokkaido University, and Hokkaido University repatriated 14 ancestral human remains to the Association of Kotan including Mr. Ryukichi Ogawa who is a representative of Ainu descendant family in July 2016. Following this repatriation according to settlement proposals by the Sapporo District Court, Hokkaido University repatriated 82 human remains to Urahoro Ainu Association in August 2017 and 4 human remains to Monbetsu Ainu Association in September 2016.

In Japan, the correspondence of the government for this issue was extremely slow, and the government began to examine it after 2009. The MEXT had understood the number of Ainu ancestral remains in Japanese universities in 2013. In this moment, the Council for Ainu Policy Promotion is considering the guideline on the procedure for repatriation of human remains from universities to local communities. On the other hand, it was recognized that Ainu ancestral human remains are stored in overseas museum such as Germany and Australia in 2016. In June 2017, the Australian ambassador in Japan visited the Hokkaido Ainu Association and declared that three Ainu human remains in Australia National Museum and Museums Victoria in Australia can be repatriated to Japan. In July 2017, One Ainu ancestral human remain repatriated to the Hokkaido Ainu Association from Berlin Society of Anthropology, Ethnology, and Prehistory for the reason that it was collected illegally by a German traveler in 1879 from Sapporo, Hokkaido. However, the whole picture of Ainu human remains collection in the world is still unclear, and it is necessary to continue systematic survey with international collaboration.

There are unsolved issues on the repatriation of Ainu ancestral human remain. One of the key issues is the debate over the National Keeping Place. The government decided to build the National Keeping Place to gather and memorize the unknown remains to the repatriate destination.

In response to this decision, some community members have opposed the aggregation, and voices have been issued calling for the repatriation to the communities.

The second is a discussion on the handling of the Ainu ancestral human remains from archaeological excavation. Currently, in Japan, all of excavated archaeological finds are protected by Act on Protection of Cultural Properties. However, there is no provision in the act that refers to the handling of the ancestral remains and grave goods for the Ainu. According to the current legislation, excavated archaeological finds which dated before 1868 are classified as archaeological cultural property. Therefore, if there is no claim of ownership from descendant family, the Ainu ancestral human remains have ownership of the government as cultural property and have a right to be managed by the local government.

According to UNDRIP, the rights of indigenous ancestral human remains and sacred objects belong to indigenous peoples. In this context, Japanese legislation needs to add clauses that clearly recognize ownership of the Ainu. In Japan, the issues between indigenous rights and cultural heritage still remain unsolved (Kato 2017).

Future Directions for Indigenous Archaeology in Hokkaido

Japanese government officially recognized the Ainu as indigenous peoples in 2008. For this reason, it has not been studied the development of laws to ensure a right for the Ainu as indigenous peoples. The question of who owns the past is an important subject in the archaeology of Hokkaido Island (Fig. 6).

The concern is that Ainu are not sufficiently guaranteed the opportunity to participate actively in preservation and use of cultural heritage in Hokkaido. While internationally there is increasing engagement with indigenous peoples in the preservation and utilization of cultural history, there has been relatively little discussion and action on this front in Japanese archaeology. In order to promote discussion and action in the direction of increased engagement with Ainu, it is necessary to consider the contemporary context. In Hokkaido, a place with a polyethnic past and present, archaeologists should aim to develop heritage protection and management programs that involve indigenous and nonindigenous stakeholders as equal partners.

Although it is one step at a time, it is beginning to create a basis for the practice of archaeology involving the perspectives of the Ainu and fostering researchers from Ainu people in Hokkaido. In 2005, Hokkaido Ainu Association, the Anthropological Society of Nippon, and the Japanese Archaeological Association organized the round table for future research on Ainu human remains and grave goods and reported critical reviews for the past Ainu studies. This report was compiled in 2015 and reported at the Council for Ainu Policy Promotion in April 2017. In this report, it was recommended the necessity to establish a committee for the research ethics on the Ainu studies. A committee for preparation of research ethics will be organized by Hokkaido Ainu Association, the Anthropological Society of Nippon, the Japanese Archaeological Association, and the Japanese Society of Cultural Anthropology and begins to study in 2018. In April 2019, the first graduate school of Ainu study and indigenous studies in Japan will be established at Hokkaido University.

We well understand that "archaeology is a powerful tool in the creation of cultural identities in the past" (Smith and Wobst 2005: 14). Archaeologists should recognize that they cannot exist without a partnership with regional communities (Kato 2010, 2017).

Université d'Abomey-Calavi,
Abomey-Calavi, Bénin

Introduction

Augustin F. C. Holl is an African academic and archaeologist. A Cameroonian national naturalized French citizen, progressively established and well-known scholar in Africa, Europe, and the USA. This is not to omit his Chinese prominent implantation since 2017 as resident Distinguished University Professor at the Xiamen University (Fujian). His research centered around the emergence and development of food production and social complexity essentially in Africa but also elsewhere. This is done with a balanced complementary interest in the Chalcholithic as transitional technical phase (in Southwestern Asia and Europe) to the palaeo-metallurgic ages. With such techno-cultural sequenced professionalism, the risk might be taken to say that he is specialized in the "Neolithic" processes and periods, despite the increasingly questioning of the relevance of this concept in Africa and elsewhere. His fieldwork and intellectual accomplishments make him to be inclined towards trans- and multidisciplinary archaeological practice and theory.

Thus, Professor Holl stands a synergic team making and/or adherent researcher, first during his 1980s' nurturing professionalism at the long term well-known "Neolithic" Dhar Tichitt site in Mauritania, then in conducting the Houlouf Region Project (1982–1991) in Northern Cameroon, the Mouhoun Bend Archaeological Project (MOBAP 1997–2000) in Burkina Faso, and the Sine Ngayene Archaeological Project (SNAP 2002–2010), and the Xiamen University Saloum Delta Shell-Midden project (2017–present). In parallel, he was aptly involved in the Chalcholithic Negev Project in Northern Negev in Israel (1984–1996), conducted an Ethno-archaeological Project on Shuwa-Arab pastoralist settlements (1986–1988), and was as well member of the New York African Burial Ground Research Project (1993–2006).

His aptitude as archaeologist trained in palynology and faunal analysis, combined with multifaceted experience in excavation of a wide range of archaeological sites, allowed him to become a synergic "pilot" of multidisciplinary training and excavating teams. In addition, he is of a versatile intellectual competence that facilitates his teams' tasks of testing ideas formulated in field reports, co-authored articles and edited books. I had such positive experience personally as author of the

chapter on the "First technical and cultural complexes: characterization and classification," in the UNESCO's *General History of Africa. Volume IX*, completely edited by him since 2018.

Major Accomplishments

On His Research Programs and Topics. After the successful completion of his PhD (Sorbonne 1983), A. F. C. Holl became Assistant-professor, promoted to Associate-Professor in 1988 at the University Paris-X Nanterre. Thanks to his affiliation to a CNRS laboratory, he was able to launch his programs combining teaching in one semester and field research in the other. His research interests range broadly within the domain of anthropological archaeology and touch on material culture and technological change, the emergence of complex societies, mortuary archaeology, rock art, the emergence of food production; archaeology of African diaspora (New York African Burial Ground Research Project); West African archaeology, Prehistoric adaptation to marginal dry lands; Sahel, Sahara (West Africa) and the Negev desert (Israel), and Ethnoarchaeology of pastoral societies.

These topics were addressed systematically through regional archaeological research projects in Mauritania (Holl 1986) Cameroon (Holl 2002, 2003), Israel (Levy et al. 1991), Burkina Faso (Holl 2014), and Senegal (Holl and Bocoum 2017). Field-based research was complemented by forays into broader topics, the advent of metallurgy, Saharan rock art, West African early urbanization, and Bantu expansion (Holl 2004, 2006, 2009, 2017).

Holl's major accomplishments in individual and/or co-authored publications are mostly related to the results of the field investigations he conducted or was involved in. As to be seen with a selected list of detailed references below, all his projects were published in monographs: *Economie et Société Néolithique du Dhar Tichitt* (In English, viz., *Neolithic Economy and Society at Dhar Tichitt*) (Holl 1986), derived from his doctoral field research at the Dhar Tichitt; *Ethnoarcheology of Shuwa-Arab Settlements* (Holl 2003) and *The Land of Houlouf: Genesis of a Chadic Polity* (1900 B.C.–1800 A.D.) (Holl 2002) related to the Houlouf Archaeological and Ethnoarchaeological project (Sahelian Northern Cameroon); *Archaeology of West African Mounds Clusters* (Holl 2014) for Burkina Faso project, and *Megaliths, Cultural Landscape, and the Production of Ancestors* (Holl and Bocoum 2017), to mention a few examples.

An additional illustration is a co-authored article titled "Subterranean Negev Settlement" (Levy et al. 1991), which derived from ca. 4500 to 3700 BC data from the Chalcholithic Negev Project in Northern Negev in Israel. It is equally useful to mention two articles not hereby directly linked to specific field project results, one in what is scholarly called archaeometallugy (Holl 2009), and the other, belonging to the interrelated topics of migration and settlement in archaeology, entitled "L'Expansion Bantoue: Une Nouvelle Synthese" (In English, viz., "Focus. The Bantu expansion: old questions, new data") (Holl 2017). The intention and the chief interest in mentioning here and now this migration and settlement twofold topic is to making a topical connection with a recent and important "China-Global-Video Conference" that resident Distinguished Professor A. Holl delivered on 13 November 2018 (Fig. 1). Such connection is made chiefly in order to remind, in African Archaeology and History, the scholarly commitment to tirelessly updating the long lasting debate on the "Bantu origins and expansion." Hereby, A. Holl did not miss to play his part of the game in focusing the worldwide video conference on such challenging French stylistic terms as "Les langues bantoues ont conquis l'Afrique à travers des migrations" (In English, viz., "The Bantu languages have conquered Africa through migrations").

This latter project, the Xiamen University Saloum Delta Archaeological project (2017–present), related to his newly appointment as Distinguished University Professor at Xiamen University (Fujian, China), launched as field-school for Chinese and Senegalese students, is

Holl, Augustin F. C., Fig. 1 Professor A. F. C. Holl speaking at Xiamen University (Fujian, China). (©GlobalGeoPark)

the continuation of his life-long dedication to undergraduate training (Fig. 2). Such active, worldwide, and multisided field investigations associated sometimes with students' training exercises, are together inductive of a synergic impact on his multicontinental academic, administrative outstanding accomplishments.

About His Institutional Career. After the successful completion of his "Habilitation-Thesis" in 1994, Holl's academic career took a different, exciting, and unplanned turn. He was offered successive appointments in leading research institutions. As a result, from 1997 to 2019, the picture is that of interinstitutional and transcontinental promotions. In 1997 onwards, he moved from France to the USA where he was appointed, successively, Professor of Anthropology at the University of California, San Diego, then Curator of African Archaeology and Professor of Anthropology and Afro-American and African Studies at the University of Michigan, Ann Arbor. In 2011, he moved back to Paris (France) where he resumed his academic career as Professor of Prehistory at the University of Paris – Nanterre-La Defense. He was appointed vice-president in charge of International relations the following year, and Deputy-Director at the Institute of Social Science and Humanities, of the Centre National de la Recherche Scientifique (CNRS) in 2015. As a fortunate continuation of his institutional academic promotions, he was offered the exciting position of Distinguished University Professor at Xiamen University (Fujian, China), with the prestigious administrative job of founding Director of a multidisciplinary Africa Research Center. He resigned from the CNRS to settle in China in February 2017.

As the illustrative consecration of his ascending intercontinental academic career, he was selected as the Chairman of the International Scientific Committee of UNESCO General History of Africa (Vol. 9–11) at its first session in 2013 in Brazil, for the drafting and the publication of the book. This project started in 2013 under the auspices of the African Union's Heads of states and UNESCO's Council. It was initially focused on the writing of a *General History of African Diasporas* worldwide. The Republic of Brazil, then under President Lula Da Silva and Dilma Rousseff tenures, provided substantial funding to ensure both the drafting and the publication of the additional three volumes. The initial project was thus amended by the scientific committee to revisit and update the preceding eight volumes published from 1980 to 1999.

Basic Biographical Information

Augustin F. C. Holl was born on March 22, 1954, at Edea in Cameroon (Africa). From age 6, he started moving with his civil-servant parents to a different city almost every 2 years. In order to successively complete his middle and high school, he went to boarding school, and graduated in History and Anthropology at Yaounde

University. In 1979, he went to graduate school at the University Paris-I Pantheon Sorbonne where he completed his PhD in 1983. He earned his HDR (Habilitation to Research Supervision) in 1994 at the University Paris-X Nanterre. As graduate student, in order to aptly handle his Prehistoric Economy research project on the "Neolithic" economy of Dhar Tichitt (Mauritania), he got trained in palynology and faunal analyses. As graduate student supervisor, he participated in field research projects in the Aisne Valley in France and Blicquy in Belgium. His doctoral field research at Dhar Tichitt was supervised by Professor Henry-Jean Hugot in February–April 1981. He completed his field research and defended his dissertation 2 years later in May 1983. He was married twice and has four children.

Holographic Epistemology: Native Common Sense

Manulani Aluli Meyer
School of Education, University of Hawaii at Hilo, Hilo, HI, USA

> Research in a Maori sense seeks to expand knowledge outwards (tewhanuitanga); in depth (tehohonutanga); and toward light (temaramatanga) (Mead 2003). Knowledge is embedded in the culture of the people. Knowledge comes through in the lives of the people. (Una Nabobo-Baba, Fijian)

Introduction and Definition

In ancient systems around the world, there are inevitably three main ways in which to view and experience knowledge: (1) via the objective, physical, outside world, the world of science and measurement and density and force; (2) via the inside subjective world, the space of thought, mind, idea, and interiority that helps us understand meaning and our linkages with phenomenon; and finally (3) via the quantum world shaped by transpatial descriptors and intersections, a spiritual dimension unlinked to religious dogma, described in ethereal, mystic, and yet experiential terms, i.e., *All my relations* or in science the *Implicate Order* – simply put, *body, mind, and spirit* or in Maori, *tinana, hinengaro, and wairua*. Hawaiians refer to this epistemological trilogy as *manaoio, manaolana*, and *aloha;* Fijians see it as *vuku, kilaka* and *yalomatua*.

The challenge is to not see this trilogy as a linear sequence, rather as an event happening simultaneously and holographically. A hologram is a three-dimensional photograph made with the aid of a laser. To make a hologram, the object to be photographed is first bathed in the light of a laser beam. Then a second laser beam is bounced off the reflected light of the first, and the resulting interference pattern (the area where the two laser beams commingle) is captured on film. When the film is developed, it looks like a meaningless swirl of light and dark lines. But as soon as the developed film is illuminated by another laser beam, a three-dimensional image of the original object appears. The three-dimensionality of such images is not the only remarkable characteristic of holograms. If a hologram of a rose is cut in half and then illuminated by a laser, each half will still be found to contain the entire image of the rose. Indeed, even if the halves are divided again, each snippet of film will always be found to contain a smaller but intact version of the original image. Unlike normal photographs, every part of a hologram contains all the information possessed by the whole (see Talbot 2011).

In and of itself, each category exists potentially untangled and separate. Here is the state we are now in within classical physics and our current scientific epistemology. Objectivity is divorced from subjectivity and both are synonyms for the hard/soft sciences, while the topic of spirituality has become a pink crystal New Age embarrassment to all forms of science. The trilogy has become a dysfunctional family. Here is where we heal. *Right here*.

> Quantum Mechanics has established the primacy of the inseparable whole. For this reason, the basis of the new biophysics must be the insight into the fundamental inter-connectedness within the organism as well as between organisms, and that of the organism with the environment. (Marco Bischof)

If we are to alter and explore a more robust version of reality, then here is where our suspension of disbelief can be practiced. Here is where faith in wholeness and interconnection is rigorously definitive. Here is where indigenous realities, contexts, and understandings can benefit from cross-fertilization with Western classical sciences because a hologram is made with modern techniques but its implications are best understood with an ancient mind: *The whole is contained in all its parts* (Nadeau and Kafatos 1999). Body/Mind/Spirit is one idea. Or as quantum physicist David Peat explained, *The ground out of which matter emerges is also the source for consciousness*. Here is a (k)new idea we can all investigate together. Holographic epistemology thus helps us better understand the depth and rigor of an indigenous mind, but first we must understand our own (Mahalo to Dr. Shane Edwards of Te Wananga o Aotearoa of New Zealand for this idea of (k)new. It was found in his Ph.D. dissertation: *Titiro Whakamuri Kia Marama Ai Te Wao Nei: Whakapapa Epistemologies and Maniapoto Maori Cultural Identities*. It summarizes both the feeling and fact of the idea of ancient/new).

The following table gathers in one place this holographic image, using three "laser beams" to bring out facts, logic, *and* metaphor to help us get to this "inseparable whole" we have known all along exists. It is separated now for discussion only and only for a moment! (Table 1).

Is this idea of a hologram using three "beams" clear for you? Look at the list again. *See it with your own expansive awareness*. Lend your consciousness to its purpose and you will intersect with my own, across space/time, and we will be in sync with each other. Familiarize yourself with the three categories: Body, Mind, *and* Spirit. Do you hear their distinctive harmonics?

Do you see how the location of the idea describes the boundaries/freedom of that idea? No judgment here, just an observation of what the physical plane offers, what the mental plane offers, and what the spiritual plane offers. Here is a radical and profound simplification of a (k)new world epistemology Indigenous people and allied scholars are putting forth. Ken Wilber (2001) refers to this trilogy as The Big Three. Hale Makua (2004), Hawaiian elder-mystic, called it the Three Souls. It is found in the Tao Te Ching, chapter 42:

> The Tao gives birth to One.
> One gives birth to Two.
> Two gives birth to Three.
> Three gives birth to all things.

I had once referred to this process and thinking as the Triangulation of Meaning (Aluli-Meyer 2008). It was meant to bring coherence between the three operating principles, but it gave the impression of a linear sequence and unnatural hierarchy. I had initially thought that information came first in some kind of text or noun form, then it was experienced and *then* it was understood. Here is the dilemma of our schooling system. For years I've been trying to understand what happens simultaneously and yet it was described as a sequence, the lock-step approach found in modern expectations more interested in quantity, control, and time rather than *quality, consciousness* and *space*.

I now see these sets of three as holograms to collect, play with, and trade with others. There is a clear knowing that each beam in the hologram is necessary to bring forth the fullness of its essence, form, and purpose. See, there it is again: Mind/Body/Spirit. A holographic approach to knowledge has changed everything in my own life and scholarship. It is no longer simply about *technical rationality*, as Henry Giroux (1988) has detailed. It is about *hermeneutic rationality* and *emancipatory rationality*. It is about my own authentic interpretation and the freedom experienced when I render it clearly with an interest, reverence, and understanding of context/content. That has indeed changed *everything*.

Key Issues

Three Whole Ideas: *Separately*

Body: External, Physical, and Objective Content

Context is the content (David Hawkins).

Context is within. Content is external (Roxanne Kala, Native Hawaiian).

Here is one laser beam in the hologram we know how to operate. It is the beam we are most familiar with and the projection we can recognize, even if it only makes the understanding two dimensional. The physical/body aspect of holographic epistemology is the foundation of Science, of classical Physics, and of positivism and all its empirical measurements and verifications. The physical world is an outside phenomenon we experience through our senses. It's our scraped and bloody knees from a hill we knew would thrill us. It's the flash of light you saw come before sound and boats listing at low tide. It's the weight of a premature baby in your one hand. It's the color blue in sky and water we knew quickened our pull for outdoor play.

Fundamental objectivity is also the basic ground for an Indigenous knowing because experience, over time/space, cannot occur without awareness of that which is physical, external, and the interacting agent grossly encountered outside oneself. The physical aspect of holographic epistemology is knowledge that comes from direct experience, a knowing because it has been encountered, registered, and remembered in bone and muscle. It is also knowledge gained by the full spa treatment of a scientific regime: time, weight, mass, velocity, etc. The physical world is a world that can be predicted, controlled, and shot into space. It extends the life of our hearts and kidneys and cloned itself by its own hand.

Indigenous scholarship is simply asking for an evolution of this idea with the heightened rigor of a just-as-real subjective and spiritual/quantum reality (aka *culture*) we know exists and indeed celebrate. It is a call for critical consciousness and respect for other way of knowing. It is what enduring practices in place have developed and processed: a knowledge ethic shaped by the needs of place and people. Here is *cultural empiricism* so to speak, altered by seasons, the sharing of ideas with others, and with its own referential knowing steeped in ancestral memory. It is also real, alive, and part of the external world – we just have different priorities and names for how we experience and express it.

Mind: Internal, Mental, and Subjective

> We must assume behind this force [in the atom] the existence of a consciousness and intelligent mind. This mind is the matrix of all matter. (Max Planck)

> The electron does not have objective properties independent of my mind. (Fritjof Capra)

> The great consciousness exists in my mind. (Oscar Kawagley, Yupiaq)

Here is the laser beam we squirrel away as intimacy unshared, a light we believe separate from quantifiable observability and our own bodies. Mind is the culprit in a qualitative quagmire and forever in some kind of conflict of interest. Subjectivity is the stain science and research has not yet been able to wash away. The mind category of our holographic/indigenous epistemology is the relative truth of what is not seen but yet available via thought, idea, and reflection. The mind beam in our hologram is about insideness, about the richness and infinity of difference found in our own humanity. Mind illuminates experience and brings forth meta-conscious awareness and purpose to detail meaning and interconnection. It is the maturing agency of collective and individual *thinking*. Without paper and pencil, without clock, and without competitive comparisons – a thinking that inspires what Maori have called aromatawai or self-reflection that instructs and transforms. Paulo Freire (1970) called this revolutionary process of waking up *conscientization*, while Teilhard de Chardin called it *hominization* vital to the larger transformations of society, this capacity to reflect, to think, and to *use* our minds.

Mind in this discussion is not the firing of neurons in our brain. It is the capacity to review an idea, to link what is known to new patterns, and to offer fresh understanding to reoccurring problems. Mind is the inside capacity that recognizes variations and brings forth their logic with symbols of shared meaning. It is the same as body, just from an inside vantage point. Hawaiians refer to this idea as naau or stomach region. It is the root word for wisdom, naauao, which means "enlightened intestines." I know, this idea may be hard to consume, but we must at least agree to its presence and legitimacy. *Mind matters*. It is the inside agency of body and the connecting essence of all that is material.

> Sensations originate in the body but it is the mind that experiences them. We say emotionscome from the heart but it is the mind that is aware of them. (Francesca Freemantle)

How one develops mind is the focus of this entry. Do you see it separate from body? Do you see mind as a hindrance to technical rationality? How one sees mind is perhaps the turning point of self-reflective subjective awakening. Remember, mind is one part of the trilogy necessary for our hologram to be fully operational. It is no less valuable, no more valuable than any of the other beams. It is what Indigenous scholarship brings forward as a segue to spirituality. We develop

awareness through the mind/body of our own selves, and here is where the simultaneous immersion into quantum realities changes everything. From the beginning of space it has been this way. Don't you think it's *time* to understand it?

Spirit: Transpatial, Nonphysical, Culture

> At this point, the rational, conceptual aspect of the mind must let go, allowing a breakthrough into direct, intuitive experience. (Fremantle 2001)

Ulua'ekewelina a ke aloha. Loving is the practice of an awake mind.

> Life, being an ascent of consciousness, could not continue to advance indefinitely along itsline without transforming itself in depth. It had, we said, like all growing realities in the world, to become different so as to remain itself. (Teilhard de Chardin 1959)

It is time/space to speak of the spiritual dimension of life. Do not curl away in antireligious dismay or leap into dogmatic exaltation. This discussion of spirituality is not a religious idea; *we just think it is*. Shake that belief off and clear your mind. Wairua/wailua is as real as the tangible and mindful realms. It has been proven, stitched, sung and experienced that *we are more than our bodies* (Near Death Experience (NDE) summary/lesson from L.M.S. of Pepeekeo, Hawaii, after drowning accident and immersion in coma at Hilo hospital, 2009) and more than our minds. *Matter is not separate from spirit* and so here is the culminating idea of this chapter and the animating third beam that Indigenous scholarship confirms. It is the laser that popped images into three-dimensional holograms surprising the world with its implicate wholeness, even as shards splintered on scientific floors across the planet and we discovered *the whole of life is found in all parts*. That is as much a physical and mental idea as it is a miracle of the quantum world. For many Native peoples, this is basic common sense. It is a *culture* shaped around an environment and the specific needs of people.

Many synonyms exist for this idea of dynamic interdependence; this field of mind enmeshed within body as the causal agent in an unseen reality we have direct access to and indeed are the shapers of the implicate order, self-organizing systems, auamo kuleana, coherence, non-seperability, fundamental character of reality, dependent co-arising, akashic field, paticca samuppada, interdependence, systems theory, mutual causality, holographic epistemology, complimentarity, the Divine Milieu, entanglement, makawalu, milestone of human thought, whakapapa, Indra's net, the blanket, undivided wholeness, and Indigenous epistemology.

Buddhists call this matrix the *expressible content of enlightenment* and their scientific collaboration is helping us understand our role in its creation or demise. The transpatial, contemplative, intuitive, loving, mystic, still, and joyful dimension is the on switch of our lives. It's the third laser beam that makes sense of the other two. In science it is an event horizon of knowledge that is causing a rethinking of classical epistemology and classical physics. Do you understand this idea? We are all three realms: Body, Mind, *and* Spirit – but we must be conscious of it to actualize them. Slow down, take a breath. Physical/mental/causal – three facets of one idea. *He 'ikekaihohonu* – here is deep ocean knowing.

The perceived contradiction is that spirituality has developed its own bureaucracy in the form of Religion and thus it has become an invalid source of scientific inquiry. Is it any wonder we ritualized our awe and gathered en masse at unseen mysteries? Science needed to pull away from dogma and what was labelled as superstition; it is part of our shared history. We are not talking about returning to this way of viewing the world. What Native intelligence as an enduring pattern of thinking is putting forth with the aid of quantum sciences is the notion that a realm of unseen connecting patterns exist and we are the causal linkages that alter its capacity. There is a new/old game in town. It must include what has forever been present but denied because of the beliefs of the day. As always, Indigenous peoples are near – watching, waiting, and ready to be of service.

Indigenous World Views

> *Makawalu* – A Hawaiian interpretation and practice of interdependence

> The depth of relatedness is so powerful that it guides our lives. It is our Law. (Karen Martin, Aboriginal)

> Wisdom is the recognition of the interdependence of things. (Sulak Sivaraksa)

An Indigenous world view thus begins with the idea that relationships are not nouns; they are *verbs*. This basic notion of relationality, dynamic coherence, interdependence, and mutual causality helps us see the *context* of an idea and people, tangible or not, and respond appropriately. The hard part of this notion is that you can't weigh verbs, well not really. Relationship as verbs infers the *intentional quality* of connection that is *experienced* and remembered. Here we begin our walk into Indigenous epistemology, into the simultaneity of the unseen and seen. We are entering a wide-open field of knowledge production and exchange with priorities in *practice, relevance, context, consciousness* and *shared common sense*. It is knowledge through *experience* individual or collective, and a way of being via site-specific familiarity through years, generations, and lifetimes. In this way, patterns emerge collapsing time into space and all unknowns into mystery and story. It is knowing shaped by purpose and knowledge prioritized by function. Finally, it is an understanding that has *endured* for a *reason*.

An Indigenous Weltanschauung (world view, product of culture, constructed in language) then is indeed a challenge to bring forward because of the myopia of our independently trained minds. The vast amount of difference the world offers us is currently withering in a hailstorm of uniformity, capitalistic assimilation, and literal renditions of reality asserting a predictable empiricism now waiting to evolve. It is at these very sites of tension, however, where the future of rigorous scholarship lies. For us to move forward in the exploration of indigenous ideas and to actually *see* other views of the world, there is first a call for the suspension of currently held thought patterns, particularly around knowledge, science, and reality.

> There is a critical need for a new old way now. (Veronica Arbon, Arabana – Aboriginal)

This entry is embedded within a global archaeology text. Archaeology as a system of science has brought specialized facts of humanity and cultural practices to the world and as a field worked to articulate the connection of people to place, history, and ideas. There are infinite ways one can portray a people, knowledge, values, or culture. Archaeology has historically privileged the technical form of rationality and strengthened the view that objectivity and measurement is the accurate and best way in which to engage and explore peoples. *That is a world view*. It is tutored by the expectations and values of a cultural system, a language, and the political/economic climate of the times. I believe Indigenous people share the same view, just *differently*.

Indigenous is simply a synonym for *that which has endured*. It is not a nostalgic or romantic cast over objective data, nor does it dismiss what modernity has thrust upon us. It is a way of behaving that offers us older ways to view the world. It is not meant to operate in lieu of but rather to synergize with classical views of science and now with a quantum world already dreamed of, debated, and woven into art forms of function, reliability, and beauty.

(K)new Science: An Indigenous Perspective

> The perspective of Native science goes beyond objective measurement honoring the primacy of direct experience, interconnectedness, relationship, holism, quality and values, and they are specific to tribe, context and cultural tradition. (Cajete 2000)

Science, the process to understand our natural world, is not a new idea; it is old. How it now unfolds within a mathematical, technical, capitalistic, and positivistic structure is relatively new. Engagement and meaning-making with our world is an evolutionary process, always present, that accelerates or expands with mature, conscious, and rigorous *reflection*. The opposite is also true: the understanding of our world remains static without reflection in a field of reference that mirrors itself with itself eventually pulling away from direct experience into a self-justifying loop. This is our current situation in my own field of philosophy, and I sense even in science. We then begin to name events in isolation from others, defying

contextual comprehension born through the ages, and understood by those who have witnessed them, remembered them, and sung their lessons in the life exchanged.

> The problem is not with the empirical data of science but with the contention that these data alone constitute the legitimate ground for developing a comprehensive worldview or an adequate means for responding to the world's problems. There is more to human existence and to reality itself than current science can ever give us access to. (Dalai Lama 2005)

Here it is, a call for a comprehensive world view in which to engage an idea, an object, and a collection of artifacts. How does one evolve in this manner without exposure to other ways of thinking? It is the key challenge to address in modern society.

> Hahai no kauaikaululaau. Plant a forest and the rain will follow (Native Hawaiian).

> To gain a sense of Native science one must participate with the natural world. To understand the foundations of Native science one must become open to the roles of sensation, perception, imagination, emotion, symbols and spirit as well as that of concept, logic, and rational empiricism. (Cajete 2000, Tewa Pueblo)

Native Science practitioners do not separate mind from body, nor do they separate that from the quantum world. We are neither wistful about their union. Sensual cues, coupled with imagination and emotional awareness, sharpen ones' sense of rational empiricism; they do not diminish it. Here is the perceived contradiction Native Science offers the world: wholeness and mature understanding of systems by seeing patterns, both tangible and in thought, of concrete, quantum, and causal worlds.

> In Blackfoot, objects that we see are simply descriptions; they are collective agreements only. (Leroy Little Bear)

> When you start seeing the world in patterns instead of laws, everything opens up. Vision itself changes. (Dolores LaChapelle)

How does one enter this kind of epistemological arena where the integration of an idea is the understanding of it? To see patterns develop themselves and then intersect, fractal, and converge with others in an infinite array of evolving life. How *do* you enter this kind of thinking/seeing? Here are the building blocks of *cultural empiricism*, the kind of empiricism that begins with a different sensory immersion, a heightened sense of context, and a whole different tool belt useful in shaping cultural priorities for different understandings. How will I describe this orange with an apple vocabulary?

> The world is mind. (Vine Deloria Jr.)

Here again is the segue from indigeneity into the quantum sciences, this reckoning with simultaneity and our own role in reality production and scientific findings. When the world becomes mind, as Standing Rock Sioux world scholar Vine Deloria (1999) suggests, he is inferring the radically empirical universe William James outlined almost 100 years ago. It is a connection with the physical and nonphysical states altered by our own seeing. Einstein held the same belief that our own viewing of phenomenon changed it. Is it any wonder the Hawaiian word for knowledge is "ike," to see/to know. Seeing then is an act beyond mere looking. Seeing is infused with the cultural shaping of its *purpose* and that by itself collapses waves into particles. Yes, why not work to understand this miracle? Why not see what intentionality and consciousness have to do with matter?

Here lies the path across dangerous waters where science and culture must meet and cross if we are to develop solutions necessary for our own evolution. Here is where indigenous sits down to discuss the latest ideas in nonlocality, coherence, and the universe as a self-organizing system some have long ago called Indra's net, the akashic field, the Divine Milieu, whakapapa, and the great ancestral plan.

Future Directions

Ha'inamaikapuana: Thus Ends My Story

> A modern "ecosophy" would be about the rediscovery of meaning as it relates to our universe. It would require not only a different way of

> thinking, but also a different way of knowing and living. Such an ecosophy would build a unitary view of the cosmos in which everything is interdependent and moved by creative energy, one that views the Earth and the universe with reverence and explores our essential relationships and responsibilities there in. It would be, essentially, the philosophy Indigenous people have lived for generations. (Greg Cajete, Tewa Pueblo)

It has always been about reverence, the act of care for others and for our earth. Aloha Aina is how we refer to it in Hawaii. It is also about the energy and life force found in *meaning as it relates to our universe*. Mahalo Greg, *I love that*. It does not matter if you view land as mother or sky as father. These are simply extensions of another's world view. What matters is that you have some kind of relationship with this place we live and breathe in, and if you only have an academic one, you must at least seek those who do not. *It is the quality of our relationships that will help us evolve*.

I believe the main purpose of these ideas is to get us to *think* together – to open our minds and explore the purpose of our lives, our work, and our particular way of viewing. Why are we this way? Why are you reading this article in a Global Archaeology text? There is a reason why you found this piece of my mind. Find out what it is and go into it with your passion for science, truth, culture, and the needs of our time. *Be of service to that*. Respond with your life to the questions of your heart. Don't make it only about cognitive accumulation of information. We do not have the luxury of time. Discover what interdependence *really* means by listening to others, by watching how those who have more experience do things, and by sharing ideas when asked. Then go out and watch the moon rise and swim in waters freshly seasoned with spring rains.

Finally, here is what mentor/friend Willis Harman had to say on the subject:

> I think the wisest thing is being humble and listening. We live in a very arrogant society. Listening has to do not only with listening to myself, but listening to nature and listening to very simple people. There are things that Native Americans have said to me in just a few words that just summarize so much. I was talking with one Native American and he got a little tired of my questions and he said, "you know you white people, you have so much trouble understanding the way we Indians look at the world, it is very simple to understand how Native Americans view things, you only have to remember two things, one is, everything in the universe is alive, the other is, we are all relatives"... and that is wisdom. (Willis Harman, Institute of Noetic Sciences; http://twm.co.nz/Harm_bio.html)

So here it is: *effulgent coherence*. This is why *three ways* of our knowing must now be detailed, debated, and understood: physical, mental, and spiritual *are* aspects of our holographic universe. They operate as beams of energy teaching us in separate ways about wholeness.

Our Wholeness

Indigenous world views will thus survive. Tides come in and they go out again. *Nouns have always been verbs*. It has been like this for a long time. The Big Three exist: *see* the science in it, *think* it through carefully, and then *inspire* the world with the quality of your participation. Please, most of all *ulukale'ale'a* – create *joy in the process*.

Amamauanoa.

Homelessness, Archaeology of

Kellie Pollard
College of Indigenous Futures, Arts and Society, Charles Darwin University, Darwin, Australia
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

The archaeological study of the material culture of people who, by circumstances beyond their control or for other reasons, are classified as homeless is a recent specialist scholarly field of enquiry in the Humanities. This enquiry uses traditional field methods and field techniques of archaeological and ethnographic investigation to examine the diversity of discarded, abandoned, or still in use materials and objects that represent distinct ways of life and behavior of people who do not reside in architecturally designed housing. In the examples of major studies given below, homeless people living without conventional shelter live in diverse geographical urban and rural environments and meet classifications of socially and politically marginalized peoples (Rossi 1989; Foscarinis 1996; Amster 2004; Valado 2006). Using the methods of archaeology and ethnography, researchers in the United States (USA), the United Kingdom (UK), and Australia reveal that homeless people are innovative and follow distinctive patterns of land use and settlement systems that leave unique traces in the form of archaeological evidence which attest to the personal experiences of homelessness in the past and in the present. Researchers in the USA, UK, and Australia conceived of theoretical frameworks that illuminate how social issues like homelessness impact societies. In the major studies below, archaeological conceptualizations of homelessness draw upon colonialism (Pollard 2019), Marxism and capitalism (Rooney 2016), social investment (Kiddy 2014), and political activism (Zimmerman et al. 2010). These knowledges highlight how archaeology can inform greater community awareness and empathy; better government policies to effectively address homelessness; and educational opportunities to challenge ignorance and racism. As a methodology of practice, archaeology of homelessness is in its infancy in international scholarship and applied study. In recent times archaeologists have identified as unique the archaeological signatures that are evidence of the human experience of homelessness and regard this to be an intrinsic part of human history and present life (Zimmerman et al. 2010).

Key Issues and Current Debates

To date, major archaeological studies of homelessness have primarily occurred in high-income

countries as demonstrated by the case studies in Australia, the UK, and the USA. The scholars involved in these studies are involved in large- and smaller-scale research projects that focus on different aspects of the archaeology of homelessness.

Darwin, Australia

In Darwin, Northern Territory, Australia, a doctoral study by Pollard (2019) examined the material culture and land use and settlement patterns of Aboriginal people from remote communities in the Northern Territory who travel to Darwin for a variety of reasons (Holmes and McRae-Williams 2008; Memmott et al. 2003). When in Darwin Aboriginal people make camps in the "long grass," a local term that encompasses publicly accessible beaches and rainforests, recreational and urban parks, and bush within the metropolitan area (Day 2001). Primarily, it is Aboriginal people who choose this way of living in Darwin (Memmott and Fantin 2001), and city authorities consider living this way of life illegal (https://legislation.nt.gov.ay/en/legislation/DARWIN-CITY-COUNCIL-BY-LAWS; Northern Territory Liquor Act 2015). The term "fringe camps" is a reference to their illegal status rather than their spatial arrangement within the metropolitan area. The study examined both the past and present use of areas around Darwin (1869–2018) by Aboriginal people, elucidating continuity of living in marginalized circumstances formerly and currently over a span of 130 years. Pollard's study contributes new and innovative theoretical understandings of Aboriginal behavior in fringe camps conceptualized in a model informed by philosophy and the concepts of accommodation, engagement, transgression, and survivance. The homelessness aspect of Pollard's doctoral study was part of a broader archaeological study of the post-European contact and adaptation of Aboriginal people after European colonization in Darwin in 1869.

Pollard demonstrated that material culture at fringe camps provide insights into the dietary habits, customs, and social organization of the people who reside in them. For example, homeless Aboriginal people eke out an existence on a diet of marine, freshwater, and terrestrial bush foods using traditional ecological knowledge to supplement a high-energy diet of shop-bought processed foods to prevent starvation; those people improvise modern Western manufactured objects into objects of use to make living homeless easier such as shopping trolleys for transport and storage of personal items, prams converted for transporting and storing personal items, cotton reels for fishing lines, or generators to supply electrical goods in makeshift camps. Many Aboriginal fringe camps contain the remains of bush foods caught, processed, and eaten, as well as shop-bought processed foods eaten using a plethora of Western manufactured kitchen and cooking utensils. Pollard found that although being homeless, Aboriginal people living in the long grass prefer to eat foods with plastic utensils rather than bare hands, people maintain personal health care, and people brush their teeth. All of which is suggestive of having values comparable to people who live in housing.

Finally, Pollard's study suggests that individual Aboriginal fringe camps are unique, differ in duration of occupation, differ in purpose of occupation and rationale for habitation, and reflect the continuity of cultural worldviews in the face of ongoing colonialism. This implies that rather than wandering aimlessly around the Darwin metropolitan region, Aboriginal people make camps in strategic locations for reasons that are important to Aboriginal people's ontological frames of reference.

Tampa, Florida

In the USA Rooney conceptualized the experiences of homelessness using a Marxist theoretical framework of analysis of capitalism's transforming industrialization changes on employment conditions that impact disproportionally, wage earners on a spectrum of technical capacity, expertise, and demand. As a result, some classes of people who formerly provided labor for wages abandoned their occupations due to the inability to adapt to replacement economic opportunities, thus underwriting burgeoning homelessness. Using ethnographic and archaeological techniques and elements of a participatory action

research (PAR) approach (site data mapping), Rooney studied the behavior and material culture of homeless individuals near Tampa, who Rooney argues exist as foragers in the urban metropolis. Aspects of the material culture analysis bear striking resemblance to Pollard's study of the same including tropical environmental conditions but also dietary choices, types of personal effects, and improvised creative use of Western manufactured raw materials for personal gain. Rooney's conceptualization of homeless people as urban forager's challenges negative connotations of homeless people as itinerant's (Pollard 2019), panhandler's (Zimmerman and Welch 2011), or worse (Day 1994). As a metaphor it infers the amount of focus, strategizing, and energy homeless people near Tampa expend in the pursuit of survival using an alternative means of production in an urban context. Rooney's analysis of material culture, combined with the location of homelessness sites, suggests somewhat a degree of universality of shared values between the housed and unhoused in that the types of materials homeless people collect, use, and discard are similar to those that people in housed conditions collect, use, and discard and also in the way homeless people use space and location for strategic reasons.

Bristol, England

The United Kingdom study by Kiddy and Schofield (2011) shows how archaeology can convey the experience of contemporary homeless people in Bristol. Kiddy and Schofield used a theoretical framework based on the notion of an archaeology that is socially inclusive arguing it provides social benefits to local communities in the broadest sense. Kiddy and Schofield collaborated with homeless people to convey their experiences of homelessness to the wider community through meetings and appearances in the mainstream media. This approach facilitated a mutual reevaluation of each group's perceptions of concepts such as legitimacy, humanity, and identity. The aims of the research were multiple: to empower homeless people in research, recognize the significance of homelessness oral history as an alternative narrative of contemporary land use and settlement patterning, describe the material culture of homelessness in archaeological terms, advocate an evolving definition of heritage to include homeless sites and places in the landscape as representations of "nonconformist" lives, and, finally, evaluate how to measure "benefit" to the homeless participants in the research.

After reviewing the notion of how archaeology is defined in traditional and populist terms, Kiddy and Schofield argued for a new conceptualization of archaeology as a "broad base" with a "range of intellectual possibilities." From this viewpoint, archaeology is not a pursuit confined to the study of the remote past but is a pursuit that has relevance and application to the understanding of contemporary societies. In this sense the concept of heritage is also a community-owned and ascribed living reality (Kiddy and Schofield 2011, p. 5). In this study, six sites inhabited by homeless people were identified, surveyed, and recorded for knowledge about contemporary land use and settlement patterns. The results shed light on the everyday lives and activities of homeless people, identifying occupational variability and changes in material culture through time and across space. To facilitate the contributions of long-term unemployed homeless people in the study, field methods were adapted to accommodate their work ethics and, where necessary, substance misuse addictions. This approach enabled homeless people to have a significant role in guiding surveys and in interpreting past and present occupation histories of sites which are innovative ethos toward capacity-building homeless people.

The broader local community benefited from the findings of this study through an enhanced understanding of the reality and complexity of the lives and experiences of homeless people. This research attracted widespread academic, professional, and lay interest and coalesced the community by forging new working relationships between homeless people and other people from diverse occupations and backgrounds.

St. Paul, Minnesota

The seminal publication in the archaeology of homelessness is that of Zimmerman et al. (2010) in their study of homelessness in St. Paul, Minnesota, in the USA. The theoretical framework for this study emerged from a view that archaeological knowledge can and should be of social benefit to society. Zimmerman et al. demonstrate the potential of material culture analyses to suggest solutions to problems in the lives of homeless people. For example, Zimmerman et al. observed that empty tin cans of food are a common type of artifact on homelessness sites, yet the cans display evidence of having been torn open, without the use of a can opener. The presence of empty hair conditioner containers is another type of artifact on homelessness sites. Of these two artifacts, Zimmerman et al. argue that homeless people would get more benefit from the issuing of can openers than they would from being given hair conditioner. While the archaeological evidence shows people consume a lot of canned food, the study of their land use patterns (and oral collaborations) also indicates that homeless people do not necessarily have access to water for washing. Further, the archaeological evidence suggests that it would be a better policy to distribute to homeless people something of use and that would have tangible benefit instead of something which is of little use, since it needs to be used in conjunction with a scarce resource, and results, in archaeological terms, becoming discard. Zimmerman et al. also show that archaeology does have the capacity to suggest changes in social policy through contributing knowledge about what homeless people actually need, as opposed to perceptions of what they need, perceptions not necessarily being based on evidence.

In their study Zimmerman et al. (2010) advance a philosophical conceptualization of the potential of archaeology to inform policy making by calling for a politically aware "activist" form of practice in which archaeologists discern the social benefit to be derived from archaeological interpretation of homelessness and use that knowledge to pursue new policy outcomes which improve the lives of homeless people. Underlying this argument is the notion of accountability as the core of ethical practice and awareness that a well-designed problem-oriented archaeological research can empower local communities.

Discussion

Major archaeological studies of homelessness demonstrate new, build on existing, use innovative and creative ethos, methodology, and theories to encapsulate the diverse material and ontological realities of what it is to be homeless. Each of the major studies offers insights that can inform policy debates and popular sentiment toward homeless people in local communities.

Hominids, Earliest African

Ronald J. Clarke
Evolutionary Studies Institute, University of the Witwatersrand, Johannesburg, South Africa

Introduction

The term "hominid" in the traditional sense, and the sense in which it was used for decades and is used here, derives from the family name Hominidae which applies to humans and their ancestors as far back as the divergence from the great apes traditionally known as Pongidae or pongids.

Definition

In recent years many, but not all, palaeoanthropologists have abandoned the traditional terminology because they have accepted genetic studies which claim that humans are more closely related to chimpanzees than to orangutans and they therefore argue that it is wrong to group chimps together with orangs in the family Pongidae and that, instead, all the great apes and humans and their ancestors should be classed as hominids. They then separate off the African apes (gorilla and chimp) together with humans and their ancestors in the subfamily Homininae (which has for decades been used only for *Homo* and *Pithecanthropus* to distinguish them from the subfamily Australopithecinae). Then they further separate off humans and their ancestors as a newly introduced tribe, the Hominini or "hominins" (Klein 2009: 75).

Such a scheme has not found favor with all researchers into human origins. Some, e.g., Schwartz (1987), consider that we are not more closely related to chimps than to other great apes. Schwartz has argued that we are closer to the orangutan. Furthermore, there is no consistency in classifications based on supposed genetic distance. Stringer and Andrews (2005) and many others separate the gibbons and siamangs

(*Hylobatidae*) from the Hominidae, but Goodman et al. (2001) include gibbons not only in the family Hominidae but also in the subfamily Homininae. Goodman et al. also classify the orang, gorilla, chimp, and *Homo* together in the tribe Hominini. This was taken even further by Watson et al. (2001) who classify gorilla, chimp, and humans together in the genus *Homo*. Stringer and Andrews (2005) classified chimpanzees into the tribe Panini and humans and their ancestral relatives into the tribe Hominini, but Andrews (2015) later united chimpanzees together with humans and their relatives into the tribe Hominini. This conflicts with the reason why the zoological tribe Hominini was initially created, i.e., to include humans but exclude apes (see Klein 2009). Furthermore, while Stringer and Andrews (2005) classified gorillas in a separate subfamily, Gorillinae, Andrews (2015) placed gorillas in the subfamily Homininae.

The purpose of classification is to provide clearly defined groupings so that people know what they are talking about. The variability and inconsistency in classification listed above do not do that but have instead created confusion. Here, the established classification is retained wherein Hominidae or hominids refers only to humans and their ancestral kin going back to their separation from Miocene apes.

Key Issues/Current Debates/Examples

The search for the earliest hominids has been a challenge, not only because of the rarity of such fossils but also because the closer they are to the ape ancestor, the more difficult it is to determine whether a fossil fragment is that of an ape or an early hominid. This was well illustrated by the case of *Ramapithecus punjabicus* represented by fragmentary jaw fossils from the Siwaliks of Pakistan. During the 1960s, these were generally accepted as early hominids from the Miocene of Asia (Simons and Pilbeam 1965; Simons 1968). Louis Leakey (1962) even championed his own version of this Miocene ancestor from Fort Ternan in Kenya. He called it *Kenyapithecus wickeri* and entered into arguments with Pilbeam and Simons who considered it to be *Ramapithecus*. The Siwalik fossils were about 12 Ma, and the Fort Ternan specimen was well dated to 14 Ma. Leakey was determined to find even earlier hominids and selected several jaw fossils from Lower Miocene sites in western Kenya dating to 18 Ma ago. He named a new species *Kenyapithecus africanus* as an early Miocene hominid (Leakey 1967). At that time, "hominid" meant member of the human family. Leakey's claim was not generally accepted, and even *Kenyapithecus wickeri* was later demonstrated to be an ape. Andrews (1978) found that an ape mandible from Fort Ternan actually belonged to the same individual as the supposed hominid maxilla. *Ramapithecus* also was eventually considered to be an ape, and all thoughts of the possibility of Lower and Middle Miocene hominids were abandoned with the general acceptance of the geneticists' contention that chimp and human ancestors shared a common ancestor around 5 Ma ago. That divergence date has been put back further with the discovery of older fossils claimed as hominids, i.e., *Orrorin tugenensis* at six million and *Sahelanthropus tchadensis* at seven million (discussed below).

Questions then arise as to, firstly, whether the geneticists could be wrong, and secondly, as to whether the dates for these fossils are accurate. A third, and very important, question is the matter of how one recognizes an early hominid, i.e., what are the distinguishing hallmarks of hominids that set them apart from the apes?

When *Australopithecus* was first discovered, the fossils were for several years referred to as apes with manlike features, even by their discoverers Dart and Broom. Now, with the wealth of fossils that we have of Australopithecines, their status as hominids or human ancestors is undeniable. They have three main characteristics that set them apart from the apes, living and fossil. These are (1) a dentition that is morphologically like that of humans albeit with cheek teeth sometimes of exceedingly large size and sometimes ape-like lower third premolars, but with canines that are relatively small compared to those of apes, (2) skeletal adaptations in the pelvis and lower limbs to facilitate bipedal walking, and (3) a hand with relatively short palm and fingers and

relatively long and opposable thumb when compared to the hands of apes.

It is all or any of these features that are looked for in fossils in order to determine whether they are ape or hominid. The problem is that in the fragmentary and sometimes poorly preserved fossils available, such features are sometimes not so clear-cut and thus subject to debate and disagreement.

The earliest fossils that have been claimed by their discoverers to be hominids are *Sahelanthropus*, *Orrorin*, and *Ardipithecus*. *Sahelanthropus tchadensis* was found in 2001 in the Djourab Desert of Chad, more than 2500 km west of the fossil hominid sites of the East African Rift Valley (Brunet et al. 2002). The crushed cranium (called Toumai) was located by Ahounta Djimdoumalbaye, a member of a team organized by Michel Brunet on a paleontological survey of the desert that was once the shore of mega Lake Chad, and was digitally reconstructed by Zollikofer et al. (2005). Some partial mandibles and isolated teeth have also been assigned to this species (Brunet et al. 2005; Beauvilain and Le Guellec 2004). Although the team had located many magnificent fossils of a variety of fauna, these were the first hominid fossils from those remote Miocene deposits.

The fossil cranium was found resting on the surface of the sands which were littered with fossil bones of other animals. As there was no way to obtain an absolute age for the fossil, it was dated by comparing the contemporary fauna with that of well-dated East African sites. An age of 6 or 7 Ma was considered probable for the cranium which has been given the name Toumai, meaning, in the Goran language of Chad, "hope of life." The name was given by the president of Chad, Idriss Déby. In order to better refine the dating, the associated sediments were dated using beryllium isotopes for cosmogenic nuclide dating (Lebatard et al. 2008). The result was 6.8–7.2 Ma. Hence, the usual date suggested for this cranium is 7 Ma.

It is a small cranium and has some small teeth preserved. The most noticeable feature is the massive brow ridge. It is humanlike in its lack of anterior facial projection, its small canine which is worn at the tip, thick tooth enamel, and the anteriorly positioned foramen magnum and short basicranium which suggests that such a skull was supported on an upright walking hominid (Brunet et al. 2002). There is no resemblance to a chimpanzee, and the brow ridge is not only more massive than that of a male gorilla, but it does not have a supratoral sulcus which is a characteristic of gorillas.

Another claimant for early hominid status is *Orrorin tugenensis* found in 2000 in the Lukeino Formation of the Baringo district in Kenya by Martin Pickford and Brigitte Senut (Senut et al. 2001); it is represented by some partial limb bones, jaw fragments, and teeth and dated to 6 Ma. The discoverers noted that the upper part of the femur with the head and neck had humanlike features indicating that *Orrorin* was adapted to terrestrial bipedalism.

A third candidate for early hominid ranking is *Ardipithecus ramidus* from Ethiopia, dating to 4.4 Ma ago (White et al. 2009). A fragmented partial skeleton found in 1995 took many years of careful extraction before it could be published in a series of 11 articles in a special section of the journal "Science." The skeleton was excavated at Aramis in the Middle Awash region of Ethiopia and represented a 120-cm tall female. There is much of the skull with teeth, revealing humanlike features of short cranial base, short face, small canines, and broad mandibular corpus. The brain is small (300–350 cc) and the foot has a divergent big toe. The pelvis has ilia that are broad and short in comparison to the apes. This and other features of the limbs and spinal column led the researchers to conclude that *Ardipithecus* was bipedal.

These suggestions of bipedality coupled with the dentition and skull structure were enough to convince White et al. (2009) that they had an early hominid. There have of course been skeptics just as there were with *Sahelanthropus* and *Orrorin*. This emphasizes the problems mentioned before of how to distinguish an early hominid from an ape when the fossils are fragmentary and poorly preserved and nevertheless display a mixture of ape-like and humanlike characters. The fact remains that somewhere in Africa, there was

undoubtedly an ancestor to the earliest generally accepted hominid which is *Australopithecus anamensis* at 4.2 Ma and *Sahelanthropus*, *Orrorin*, and *Ardipithecus* represent good candidates for such ancestral status.

An even earlier form of *Ardipithecus ramidus* dating to between 5.2 and 5.8 Ma ago also comes from the Middle Awash of Ethiopia. The fossils consisting of some teeth, a partial mandible, ulna and humerus portions, a foot phalanx, and a hand phalanx were named *Ardipithecus ramidus kadabba* (Haile-Selassie 2001).

A similarly aged fossil, part of the right side of a mandible with one heavily worn first molar, was recovered in 1967 at Lothagam, west of Lake Turkana, Kenya (Patterson et al. 1970), and dated to 5.5 Ma. The Lothagam site was discovered by Larry Robbins (then a University of California Berkeley student), who, together with a small team of assistants and another student, John Yellen, was exploring the remote western shore of what was then Lake Rudolf (now Lake Turkana), in the hope of finding Late Stone Age sites for his Ph.D. research. He showed it to Ron Clarke who, realizing the great age of the fossils, brought it to the attention of Brian Patterson of Harvard, who had been working at the nearby site of Kanapoi. Patterson's team subsequently surveyed Lothagam, and, together with a significant collection of Miocene fauna, they found the tantalizing fragment of a possible hominid mandible. However, the worn molar and the fragment of corpus were insufficient for palaeoanthropologists to be sure of its status, as it might instead have been an ape. Thus, for years, it remained largely undiscussed. However, Pilbeam (1972) was impressed with its similarity to *A. africanus* and published a photograph in which he compared it to a Makapansgat *A. africanus* mandible. Fourteen years later, it was discussed in more detail by Kramer (1986) and then by Hill et al. (1992). Now that the 4.2-Ma-old *Australopithecus anamensis* has been found at Kanapoi, and with the revelations of the 4.4–5.8-Ma-old *Ardipithecus*, it seems most probable that the Lothagam mandible is that of an early hominid, possibly belonging to *Ardipithecus* or to an early Australopithecine.

Introduction

Reconstructing the lives of our closest fossil relatives is relevant to our understanding of the history of the human lineage, our biology, and our relationship with the environment. Further back in time, evidence of material culture dwindles until, at around 2.6 million years ago, there ceases to be any surviving record. Prior to this, researchers must work with the same record of fossils, sediments, and rocks as any paleontologist. For the period before 2.6 million years ago, an ecological perspective – as opposed to the archaeological one usually employed for *Homo sapiens* – is therefore necessary. But the value of the paleoecological approach is not limited to species which predate material culture. The insights to be gained from studies of trophic relationships, ecological structures, and hominin interactions with the physical environment ensure that this perspective remains important to the study of human evolution up to and including *Homo sapiens*.

Definition

Paleoecology is the study of ancient ecology. Environmental archaeology, in its broadest definition, is also concerned with the ecology of the past, specifically with an ecological approach to past human populations. The two fields are thus very similar, with the key difference lying in their scale and subjects. Hominin paleoecologists largely study fossil specimens of extinct species,

and their study spans the entirety of paleontological history. Environmental archaeology is more circumscribed, focusing on a single species typically represented by subfossil and archaeological evidence. There are exceptions to this, as in the case of the paleoecological study of subfossil specimens like *Homo floresiensis* (Flores, Indonesia) or specimens of our own species. Both fields draw upon methods from biology and geology, but paleoecology, by virtue of the nature of its source evidence, has a somewhat stronger relationship with the geological sciences, particularly the study of taphonomy (Hardt et al. 2007).

"Hominin" denotes all those species more closely related to modern humans than to their closest living relatives *Pan paniscus* and *Pan troglodytes* (Wood and Lonergan 2008). Panins and hominins shared a common ancestor some 5–6 million years ago. For much of their history, two or more hominin species have coexisted, resulting in a complex and unstable taxonomy. While different authors champion different demarcations between species and even genera, this article recognizes the genera *Sahelanthropus*, *Orrorin*, and *Ardipithecus* as stem hominins and *Australopithecus*, *Paranthropus*, and *Homo* as later, more certain forms.

Key Issues/Current Debates

Given the diversity of paleoecological research, which can include everything from isotope studies of ocean sediments through to microscopic studies of fossil teeth and computer modeling of paleoclimates, it is difficult to produce a general classification of the field. There is much ongoing debate and many questions remain unanswered, focusing at all scales from the individual site or specimen through to intercontinental studies of evolutionary ecology and dispersal of lineages and at every intermediate scale. There are four major topics in the literature, specifically:

1. Diet: what hominins ate, how they obtained their food, and the implications for anatomy, behavior, and energetics
2. Ecological interactions and intrinsic ecology: the relationships between hominin taxa and between hominins and other organisms, life history, and adaptations
3. Environment: the environmental tolerances and preferences of the hominins
4. System dynamics, agency, and cooperation

These topics are interlinked by the complex relationships between paleoecological evidence and its interpretation. A paleoecological dataset can typically be used for more than one purpose, and specific research questions can be approached in several ways through different analyses. For example, Bobe et al. (2002) used data on faunal samples from strata in the Omo Valley in Ethiopia between 4 and 1.9 million years old to reconstruct changes in the abundance of different taxa. Skeletal element counts were used to evaluate the role of taphonomic processes in producing these patterns. The resulting environmental reconstructions were then checked against evidence from marine dust records and found in part to reflect climatic changes at the time (Bobe et al. 2002). This sort of multi-proxy approach is becoming ever more common as it provides the opportunity to validate and enhance reconstructions based on a single line of evidence and to identify or reduce the impact of taphonomic bias. Research may also draw on computer modeling, studies of modern analogue environments and ecosystems, and comparative data on primates and other taxa. These comparisons may be with homologous taxa (those closely related to hominins) or analogous ones which perform similar ecological roles. The use of diverse methods has had a key impact on paleoecology. It raises second-order questions of data quality, the choice and accuracy of specific methods, and the role of theories and assumptions which are almost as important as first-order concerns about diet, environment, and ecology.

Hominin Diets

The earliest proposals of hominin diet were heavily influenced by contemporary anthropological emphases on the "humanness" of fossil specimens and the importance of hunting and meat eating in setting humans (and hence hominins)

apart from our closest relatives. Despite significant new methodological advances, such as the advent of tooth microwear studies, isotopic analyses of dental enamel and bones, and enamel microstructure analyses, scientists remain uncertain about hominin diets. Between 4.4 and 2.3 million years ago, the early hominins (*Australopithecus anamensis*, *Au. afarensis*, and *Au. africanus*, with initial signs also in *Ardipithecus ramidus*) developed a characteristic pattern of small incisors, large flat molars, thick tooth enamel, and robust mandibles which would have enabled them to eat both hard and soft, though not tough, foods (Teaford and Ungar 2000). This would have permitted a flexible diet consisting of a range of foods from savannah and forest. *Paranthropus robustus*, in contrast, may have been capable of processing more tough plant foods as well (Teaford and Ungar 2000). Later species likely made more use of higher-quality resources, perhaps including terrestrial and aquatic animal foods, honey, or tubers (Braun et al. 2010).

As more specimens of each species have been subjected to analysis, the significance attributed to intraspecies dietary variation has increased. The flexible adaptations of *Australopithecus*, and the mosaic patterns of dietary evolution in this taxon, suggest that they could have eaten a wide range of foods (Teaford and Ungar 2000), and indeed evidence for this is found in isotopic analyses of *Au. africanus* and *P. robustus* which are both more extreme generalists even than modern baboons (Codron et al. 2008). Emphasis has shifted from a focus on absolute dietary differences between taxa to one which recognizes the potential role of "fallback foods" – those which are important in times of scarcity, but which may not typically form a central part of the diet – in anatomy and ecological adaptation. Current debate centers on questions of dietary variability, niche breadth, niche overlap, and flexibility at the individual and species level. Concomitant considerations include "adequate" sample sizes, theoretical frameworks for adaptive evolution which might explain the complex relationship between food consumption and craniofacial anatomy, and analytical robusticity.

Ecological Interactions and Intrinsic Ecology

Questions of diet are closely linked to those of ecological interaction, including predation, competition, commensalism, and parasitism. Characterizing the communities at hominin sites is one priority and involves analyzing environmental context and taphonomy in an attempt to move from the paleocommunity (the species represented in a fossil assemblage) to an understanding of the living community. Studies of modern analogue communities and interpretations of an organisms' ecological niche based on that of their living relatives can be used to check or confirm these reconstructions (Potts 1998). In many cases, there is a focus on comparisons between sites or strata, as in the study by Bobe et al. (2002) of change in the dominance of suids, bovids, and cercopithecids through time in the Omo Valley. Another example is Lewis and Werdelin (2007)'s work on the ecological structure of the carnivore guild at various east African sites. These studies may help in placing hominins within a particular ecological group and in the identification of broader patterns in faunal evolution and ecology. Two examples are the "turnover pulses" characteristic of African mammal lineages which may correlate with hominin adaptive radiations or ecological shifts (Potts 1998) or changes in vegetation distributions and structures which might cause ecological divergence of hominins and panins (Hardt et al. 2007).

Closely linked to the question of the ecological position of hominins with respect to animals and plants are those of niche separation and coexistence among hominins themselves. Multiple hominin species have existed in parallel, often in the same regions and similar habitats, for all but the last few tens of thousands of years, with perhaps as many as six in certain periods (Wood and Lonergan 2008). Their classification into species and genera implies some sort of evolutionary and hence ecological separation from one another. Identifying precisely what this might imply, especially when all aspects of hominin ecology are showing increasing evidence of intra- and interspecies variability, is difficult and is an area which focuses on the synthesis of external factors (environment and community ecology) with

intrinsic ecological ones relating to life history and behavior (Senut 2007). Aspects of life history, such as lifespan, fertility, and reproductive rates may determine the long-term strategies available to hominins. They can be reconstructed for fossil species using "life history-related variables" like body mass, dental, and osteological development patterns and brain growth schedules (Robson and Wood 2008), through the application of general rules based on primate and mammal studies.

The first specimen to show a developmental pattern similar to that of extant *Homo sapiens* appears late in our history. Smith et al. (2007) identify a juvenile from Jebel Irhoud, North Africa, as this individual – but the relatively small sample size of immature hominins throws into context the issue of paleoecologists' reliance on individual specimens which may not always be representative of their populations. This humanlike pattern is not something which appears steadily from an apelike precursor. Robson and Wood (2008) note that early attempts to describe hominin life histories tend to focus on characterizing the shift from "apelike" (usually characterized by members of *Pan*) to "humanlike," but that in more recent research, it has become increasingly apparent, once again, that hominin life history variables not only change at different rates and periods but also show unique, distinctive configurations that differ from all living species. *Paranthropus*, in particular, has a pattern of dental development which sets it apart from both living African apes and humans (Robson and Wood 2008). Understanding these patterns, and how they fit with hominins' ecological strategies and niches, is thus less a question of characterizing evolution as it is of developing a more detailed understanding of each species' unique ecology. Questions of theoretical perspectives and their validity, and of how and why scientists approach hominin ecology (historically as intermediate between us and the nonhuman apes, or more recently as distinctive in their own right) are therefore central.

Hominin Environments

The interactions between hominins and the physical environment are also very important. The identity and role of specific environments which drove "hominization" or the acquisition of key human/hominin ecological and anatomical characters are of particular interest. There are two major groups of hypotheses as to the nature of the key environment. The first group focuses on simple shifts, either in the nature of the environment, for example, aridification and the expansion of grassland, or in the preferences and tolerances of hominins. The second group focuses on changes in environmental variability or evolutionary turnover, like the turnover pulse hypothesis or the variability selection model (Potts 1998). A new suggestion, focusing on spatial (as opposed to temporal) variability and the role of physical landscape rather than climate or vegetation in driving hominin evolution, has also recently been proposed (King and Bailey 2006), highlighting the role of spatial mosaics in environments and of rough topography in providing resource-rich refugia and tactical advantages over predators.

These environmental hypotheses are usually based on theories of the way(s) specific contexts might influence hominin precursors living in them, but they are closely tied to paleoenvironmental evidence from fauna, flora, geology, isotopes, and sediments for validation. Such studies are responsible for recent proposals which highlight the role of forests in generating hominin traits, as studies of the stem hominins *Ardipithecus*, *Orrorin*, and *Sahelanthropus* have suggested that forests and lakesides, rather than open plains, were typical of their localities (Senut 2007). Later species have been found in a variety of contexts, and questions today center not just on the nature of habitats but on the role of taphonomic bias and preservational factors in generating observed patterns in distributions and habitat associations (King and Bailey 2006). Fossils are often found in lake and river sediments, because these are the places where deposition is common and preservation most likely. A range of paleoenvironmental methods, modern analogue studies, and modeling techniques are therefore used to contextualize specific sites. This enables researchers to fill the gaps left in the fossil record by taphonomic bias, transport of remains, and

uncertain dating (Potts 1998). Later studies often focus on the role of coasts and other environments as dispersal routes for *H. erectus* and *H. sapiens* and the interactions of *Homo* spp. with the environments and ecosystems they encountered.

System Dynamics, Agency, and Cooperation

Much of the seminal literature on hominin paleoecology actually predates the word "ecology" and is closely linked to broader paradigms in biology and archaeology. Alfred Russel Wallace's paper on the origin of human races mounts a powerful challenge to the coevolutionary model presented in Darwin's *Origin* (Wallace 1864). Wallace argues that advanced cognitive skills effectively enabled humans to evade the universal effects of natural selection. In his later writings, notably *What is Life*, Wallace argues that this intellectual and technological liberation cannot be explained in purely scientific terms and infers the existence of a universal intelligence comparable to Henri Bergson's *élan vital*. Wallace's idea undermines all those chapters in Darwin's *Origin* that deal with cooperation and creative synergy. Wallace seems to have believed that only humans, with their superior intelligence and technology, could set natural selection in abeyance and influence the course of evolution.

Charles Darwin's *Descent of Man* presents a naturalistic model, which the older Wallace and Bergson rejected. Darwin believed higher cognitive function may actually have reduced the relative fitness of some individuals but would have persisted if it increased the fitness of the community in which the individual is embedded. Similar arguments are made in *Origin*, where Darwin discusses the coevolution of humans and their domesticated commensals and of plants and their pollinators. An insect that can only feed from rare, long-throated flowers, for example, may not enjoy the same reproductive success as a generalist but can persist as long as the community of plants and insects maintains the fitness of all. This difference of emphasis between Darwin and Wallace prefigures the twentieth-century tension between neo-Darwinists (who favor Wallace's model) and coevolutionary ecologists, who allow for the possibility that selection pressures can be mitigated by interspecies cooperation. This anticipation is all the more remarkable when one observes that Thomas Henry Huxley argued for a stick-slip model of evolution, which anticipated Hugo de Vries' later work on "mutationism" and later twentieth-century theories about "punctuated equilibria."

Although some of the key concepts of later twentieth-century systems ecology were well documented in the 1860s and 1870s and discussed almost continually since, the ideas did not become scientifically respectable until the 1960s and 1970s, when an innovation cascade fueled by postwar perestroika and the development of new computer methods led to a partial rehabilitation of Darwinian complexity. The first scholarly biological papers to explicitly use the word "coevolution" date from the 1960s; research on behavioral ecology and ethology that had been the preserve of natural historians and amateurs now came into the scientific mainstream, and models of stick-slip evolutionary dynamics and continental drift were rehabilitated. Although some textbook and popular literature presents this as a cascade of scientific discoveries, the primary sources are more consistent with an institutional veto that pushed complex dynamics beyond the pale, as it were.

In archaeology, this innovation cascade produced a number of confusing hybrids that tried to meld classic and complex approaches. It is helpful here to distinguish large-P from small-p processual archaeology. Large-P processualism had been a hybrid of classic and complex systems approaches that strove to link new developments in anthropological archaeology to classic science, particularly to Karl Hempel's concept of the scientific law. Small-p processualism or "new archaeology," on the other hand, was a more pragmatic attempt to integrate systems ecology, new scientific methods, and anthropological archaeology. Thus, by the time Lewis Binford (1981) published his research on taphonomy and hominin ecology, he had publicly repudiated his earlier processual polemics, rejecting the quest for universality in favor of what he called "middle-range theory." By studying animal modifications of bones, Binford learned to distinguish the shearing and crushing actions that can be effected using

jaws alone from modifications that could only have been effected by hominins. By analyzing faunal data in the light of this understanding, he felt able to reject the "man the hunter" hypothesis and suggested that early hominins were scavengers. The essential feature of Binford's later (small-p) processual research was a separate effort of research on process and transformation designed to provide an inferential platform. Middle-range theory identifies inferential links between the mundane and frankly uninteresting phenomena we can observe and unobservable phenomena that interest us.

As the processual vs. post-processual debates intensified in the later 1980s and 1990s, a number of new archaeologists became interested in more dynamic models of paleoecology. Where post-processual debates often degenerated into a paradigmatic argument about agency, scale, and the relative merits of environmental determinism and agency, the dynamic approach looked for some common ground. All socio-natural systems are "dynamic" in the sense that they change, but the studies referred to here involve co-dynamic situations, where cultural and natural systems create and recreate each other. This approach invites us to consider a stick-slip dynamic in which one set of causal structures can become unstable and a new, qualitatively different type of co-dynamic interaction can emerge.

The (co-)dynamic or coevolutionary approach is rare in archaeology as a whole, but two examples can be found in Pleistocene hominin paleoecology. Bailey's (1997) Epirus Project included a study of predator-prey interaction based on a hypothesis of constant disequilibrium. The result was an individual-based "toy-world" model of plant, herbivore, and predator interaction that suggested resilience could be lost if this open-ended game of hide and seek was constrained, for example, by obstacles to dispersal. By relating these middle-range insights to climate and sea-level changes, the project was able to predict the distribution of hunting sites through space and time, including some in regions that currently lie offshore.

A second example of co-dynamic paleoecology in Pleistocene ecology is provided by Mithen's (1993) work on mammoth populations. Mithen developed a simple model of mammoth reproductive behavior and used it to show that a relatively small human cull (less than 3%) could reduce the resilience of a healthy population, rendering it susceptible to relatively minor fluctuations in predation pressure and natural disasters. Again, the focus is on resilience and co-dynamic interaction between populations. Our final example uses a more ethnographic approach to systems analysis. Like Binford, Ezra Zubrow (2005) is concerned with developing methodological protocols for interpreting patterns in space and time. Where Binford's analyses were, at a first level of approximation, a-spatial, Zubrow is interested in GIS and exploring a form of auto-ethnography. Pleistocene hominins did not use the abstract, analytic skills we deploy, but those abstract methods are based on a similar cognitive foundation. By exploring the concepts of patchiness and crowding and the ways people perceive spatial pattern, Zubrow hopes to gain new insights into paleoanthropology and the dynamic ecologies of culture.

Conclusions

Our understanding of hominin paleoecology is variable and rapidly changing. Certain topics – for instance, diet in *Paranthropus* species, the interactions of species at major sites like the Omo and Olduvai, and the environments that may have driven hominization – have been intensively studied, while others are less well known. Both direct questions about ecology and more abstract problems of taphonomy, data quality and use, and methodological validation remain under active investigation. Progress is driven by a combination of methodological advances and refinements, new fossil discoveries, novel approaches to existing questions, and synthetic "meta-analyses" that integrate data from several sources and projects. Hominin paleoecology is a highly relevant and wide-reaching field with much to contribute to our understanding of the human past.

Introduction

Homo erectus is a geographically widespread and temporally long-lasting fossil hominin species known from Africa and Asia between c. 1.9 Ma and 500 ka (but perhaps to <100 ka). The taxon

subsumes a large amount of skeletal variation, and one of the central debates concerns whether this variation should be partitioned into multiple species. *Homo erectus* was the first hominin to disperse out of Africa as well as the first to take important steps toward modern human form, development, and behavior. *Homo erectus* has traditionally held a canonical position in hominin evolution, chronologically succeeding *Homo habilis* and preceding *Homo sapiens*. However, this simple time-successive progression has been complicated by additional fossil discoveries in Africa that confirm the presence of multiple species of non-*erectus* early *Homo* (Leakey et al. 2012) as well as the temporal and geographic overlap of *Homo erectus* and *Homo habilis* (Spoor et al. 2007). Nonetheless, *H. erectus* remains the presumptive common ancestor for *H. sapiens*.

Definition

Species History and Distribution

The *Homo erectus* nomen dates to the 1940s, but fossils attributed to this species have been known since the nineteenth century. Spurred by the prevailing hypothesis that human ancestors would be found in Southeast Asia, Eugène Dubois sought and found fossils in Java in the 1890s that were recognizably nonhuman but possessed brain sizes well above those of modern apes. He assigned the material to a new species, *Pithecanthropus erectus* (upright ape-man; Dubois 1894). Subsequent discoveries at the site of Zhoukoudian in China were dubbed *Sinanthropus pekinensis* (Black 1927). Both genera, along with others named in Indonesia and South Africa, were eventually subsumed into *Homo* based on their similarities to each other and relationship to modern humans. The original species name was retained to create *Homo erectus* (Mayr 1944). Discoveries at Olduvai Gorge in the 1960s (e.g., OH 9) expanded the known range of *Homo erectus* into East Africa. The species is known from East, South, and possibly North Africa and West, East, and Southeast Asia.

Homo erectus is defined by its distinctive cranial morphology, including a long, low vault and the presence of cranial suprastructures such as sagittal keeling, an angular torus, a bar-like or arching supraorbital torus, and a projecting occipital torus (Antón 2003, 2012). The widest part of the cranial vault is low and in combination with sagittal keeling and parietal deflation gives the cranium a heptangular shape when viewed from behind. Crania display moderate to marked postorbital constriction and facial prognathism, and the bones of the cranium and mandible tend to be thick and robust, although some of these attributes scale with brain size. Brain sizes range from ~650 to 1200 cc's, with an average of ~900 cc's (Spoor et al. 2007). While there is a trend of increasing average brain size within *Homo erectus* throughout the Pleistocene, most of this range in variation is present throughout the entire temporal span of the species. The lower end of the range overlaps with other early *Homo*, although average brain size is ~25% greater in *Homo erectus* than in non-*erectus* early *Homo* (Antón and Snodgrass 2012).

Characterizing the postcranial skeleton of *Homo erectus* is a more difficult task given the paucity of skeletal remains that are definitively associated with diagnostic cranial remains and the temporal overlap with other *Homo* species. The most complete *Homo erectus* skeleton, KNM-WT 15000, demonstrates that some individuals were relatively large and probably possessed the long, linear body form associated with tropically adapted recent humans (Ruff and Walker 1993; Graves et al. 2010). As with cranial capacities, however, there is a wide range of body sizes for *Homo erectus*, with small individuals found in all regions (Antón and Snodgrass 2012), such as the small-sized individuals from Dmanisi, Georgia. South African and East African *H. erectus* are similar in size, with East African *H. erectus* ranging from 51 to 68 kg and 160 to 185 cm tall depending upon whether the Gona pelvis is included, but some of the South African remains may be as small as 30 kg (Antón 2012). The Georgian remains are 17–24% smaller (40–50 kg, 146–166 cm), although this difference may be the result of a categorization bias in Africa

that has tended to place smaller isolated postcrania into early *Homo* and larger into *H. erectus* (Antón 2012). Although previously argued to differ from earlier hominins in possessing a more modern-human-like body plan with longer legs and a less funnel-shaped rib cage, hind limb elongation appears instead to be a ubiquitous feature of hominins (Pontzer 2012). Nonetheless, overall the fossil record reveals larger average body sizes in *H. erectus* than in non-*erectus* early *Homo* (Pontzer 2012). Coupled with increased brain size, these body size differences suggest larger home range sizes and the beginning of an adaptive shift.

Homo erectus is notable for being the first hominin to disperse out of Africa, which is generally attributed to a combination of increased dietary quality, body size, and home range size (Antón et al. 2002, 2014). In particular, increased efficiency in the acquisition and processing of meat is arguably tied to increased body and brain sizes in *Homo erectus*. The discovery of the relatively small-brained and small-bodied *Homo erectus* individuals from Dmanisi, Georgia, however, suggests that increased body size may not have been a prerequisite for dispersal from Africa. In addition, microwear analyses of the Dmanisi teeth suggest they shared a similar dietary breadth as other *Homo erectus* specimens, which may imply a shift in foraging strategy independent of body size (Pontzer et al. 2011). The geographic range of *Homo erectus* within Africa exceeds that of any earlier hominin and, combined with the ability of *Homo erectus* to disperse out of Africa and colonize novel environments such as higher latitudes in Eastern Asia, points to a species able to adapt to a wide range of environments, foreshadowing the highly adaptable nature of modern humans.

The oldest *Homo erectus* fossils are found in Africa, including specimens from Koobi Fora, Kenya, dated from 1.89 to 1.7 Ma (e.g., KNM-ER 2598, 3733, and 3883; Fig. 1). Interestingly, *Homo erectus* is found outside of Africa almost from the beginning of its first appearance datum in Africa. Fossils from Dmanisi in the Republic of Georgia, for example, date to ~1.8 Ma (Gabunia et al. 2000). The ages of the Indonesian *Homo erectus* remains are less secure but nearly as old; the Mojokerto (Perning) child's cranium may date to ~1.8 Ma, a series of *H. erectus* bearing deposits at Sangiran range from 1.6 to 1.0 Ma, and the holotype, the Trinil skullcap recovered by Dubois, dates to about 1.0 Ma (Swisher et al. 1994; Antón and Swisher 2004). The oldest archaeological material in China dates to about 1.6 Ma (Zhu et al. 2004), and new dates for the Gongwangling cranium also approach this age (Zhu et al. 2015), with additional fossil remains present around 800–500 ka at Zhoukoudian (Shen et al. 2009). If the Ternifine mandibles are excluded, the youngest African *H. erectus* is about 900 ka at Olorgesailie and Daka, Ethiopia. The youngest mainland Asian remains are about 250 ka, and the last appearance datum for the entire species appears to be for Indonesian fossils from Ngandong and Sambungmacan that may date to 500–250 ka (Indriati et al. 2011) or perhaps even to 50–27,000 years (Swisher et al. 1996).

Homo erectus is associated with both the Oldowan and Acheulean stone tool industries. African *Homo erectus* fossils from the earliest Pleistocene (1.8–1.5 Ma) are often found with the core and chopping tools of the Oldowan, as are the earliest specimens outside of Africa (e.g., Dmanisi) and all of the Asian fossils (Ferring et al. 2011). The oldest Acheulean appears about 1.7 Ma in Africa (Lepre et al. 2011). The lack of the Acheulean tradition at *Homo erectus* sites in China and Indonesia has led researchers to hypothesize a different material culture perhaps involving bamboo tools in conjunction with Oldowan-type chopping tools. The fossil record shows much evidence for butchery and demonstrates that *Homo erectus* often had primary access to animal carcasses (Potts 2012).

Key Issues/Current Debates

The taxonomic debates surrounding *Homo erectus* center on how to partition the variation seen in a long-lived, globally dispersed fossil species. The paleoanthropological community remains divided on this core issue. Some researchers (e.g., Antón 2003; Baab 2008, 2016) argue that all of the Indonesian, Chinese, and

***Homo erectus*, Fig. 1** The temporal and geographic distribution of *H. erectus* localities and some important specimens. The geomagnetic polarity timescale, with normal periods in *black* and reversed in *white*, is on the far *left*. Radiometric time is indicated in millions of years on the far *right*. Within regional columns, *solid lines* on either side of site names indicate time spans suggested by multiple *H. erectus* individuals from a site; *dashed lines* indicate possible time range around a single/few specimens. Within Africa, sites are grouped from *left* to *right* as South Africa, Kenya, Tanzania, and Ethiopia; OG is Olorgesailie, OH is Olduvai Hominid, numbers on the Koobi Fora line are KNM-ER numbers, and WT15k refers to KNM-WT 15000. In Asia, the sites are grouped from Georgia to China; the earliest Chinese localities are archaeological assemblages presumed to be made by *H. erectus*. In Southeast Asia, the Sangiran box delineates the timing of the hominin-bearing Sangiran and Bapang formations; however, hominins are present only from about 1.6 Ma as indicated by S4, 27, 31 (which refer to Sangiran specimen numbers); younger overlying sediments are not (currently) hominin bearing and are not shown. In all columns, gray boxes indicate a period of temporal and geographic overlap with other species. The overlapping species are as follows: in Africa, *H. habilis* (LAD, 1.44 Ma Spoor et al. 2007); in China, archaic *H. sapiens* or *H. heidelbergensis*; and in Java, *H. sapiens*

African fossils represent the single, variable species *Homo erectus*, while others divide the fossils geographically, allocating the earliest African and Georgian specimens to *Homo ergaster*, with the Chinese, Indonesian, and some African fossils as the *H. ergaster*-derived species *Homo erectus* (Wood 1994; Wood and Collard 1999). The grounds for the latter view are both geographical and morphological, as several of the African specimens are more gracile than the Asian specimens, in particular possessing thinner cranial vault bones, although these have been shown to be allometrically scaled (Antón et al. 2007). Several conditions make *Homo ergaster* a problematic taxon. The differences between the African and Asian specimens tend to be in the degree of expression of traits, and there are African specimens (e.g., OH 9, Daka) that closely resemble the classical Asian *H. erectus* morphotype. In addition, even among researchers who advocate splitting the African and Asian material, debate exists over which fossils should be allocated to *Homo ergaster*. Others would split the material into even more species, including *Homo soloensis* for the younger Indonesian fossils from Ngandong or *Homo georgicus* for the Dmanisi material; these remain minority views.

A corollary of the taxonomic debate concerns whether or not *Homo erectus* is found in Europe. *Homo erectus* fossils may persist in Asia until the latest Pleistocene, but the hominin fossils found in Europe after 1 Ma (e.g., the Ceprano calvaria, the Sierra de Atapuerca specimens) lack the distinctive cranial morphology of *Homo erectus* and are generally agreed to represent a transitional or archaic form of *Homo sapiens* (e.g., *Homo antecessor*, *Homo heidelbergensis*). Although some researchers would allocate the earliest European fossils to *Homo erectus* (e.g., the Ceprano and Gran Dolina material at ~800 ka), most agree that these fossils represent a transitional form between *Homo erectus* and *Homo sapiens*.

Another important issue concerns the life history of *Homo erectus* and the extent to which the species had acquired the modern human behavioral package of altricial birth, a large energy-expensive brain, long juvenile dependency with relatively late reproduction, short interbirth intervals with high fertility, and a long post-reproductive life span (Antón and Snodgrass 2012). With this package humans appear to have been able to circumvent several of the key constraints that affect other primate species and are able to produce numerous high-quality offspring that experience relatively low mortality, grow slowly, and live long lives. Until recently, the juvenile Nariokotome specimen had been interpreted to suggest that much of the human package might have been in place by the time of *H. erectus*. However, recent studies of dental and skeletal development have suggested a faster rate of development and smaller adult size (Dean et al. 2001; Dean and Smith 2009; Graves et al. 2010; Jungers et al. 2016), suggesting that the life history shifts in *H. erectus* were more modest. Similarly, sexual dimorphism in body size has also been argued to be reduced in *Homo erectus* relative to earlier hominins but still greater than that observed in modern humans (McHenry and Coffing 2000), but recent evidence again suggests this is not the case (Antón 2012; Plavcan 2012). However, a certain level of cooperative breeding appears to be implied over the condition in non-*erectus* early *Homo*, and a level of secondary altriciality and developmental plasticity similar to recent humans may be implied as well (Antón and Snodgrass 2012; Cofran and DeSilva 2015). Recent work provides modest support for the idea that developmental plasticity – the ability to respond to environmental conditions by modifying development resulting in variation in adult morphology that is not genetically canalized – facilitated *H. erectus'* ability to disperse (Antón et al. 2016; Antón and Kuzawa 2017).

Introduction

Homo ergaster is a paleospecies often used to describe a subset of fossils within *Homo erectus*. Proponents generally allocate early African *Homo erectus* fossils dating from c. 1.8 to 1.4 Ma to *Homo ergaster*, mainly on the basis of smaller, more gracile crania and a lack of robust cranial suprastructures. In this schema, the geographic distribution of *Homo erectus* sensu stricto is restricted to Asian localities with a few examples (e.g., OH 9) of back migration into Africa. *Homo ergaster* includes the early African and Georgian specimens attributed by others to *H. erectus* and is therefore posited as the ancestor to *Homo erectus*, *Homo heidelbergensis*, and *Homo sapiens* (Wood 1994). However, considerable debate over the validity of the taxon exists, and there is growing support for the idea that the African and Asian specimens instead constitute a single, long-lived, polytypic species, *Homo erectus* (e.g., Rightmire 1990; Antón 2003, 2012).

Definition

Species History and Distribution

Current usage of the nomen *Homo ergaster* as a descriptor for the early African subset of *H. erectus* sensu lato differs from the original use of the name (Antón 2012). The type of the *Homo ergaster* nomen is the mandible, KNM-ER 992, from Koobi Fora, Kenya (Groves and Mazek

1975). The original paratypes included other remains often attributed to *H. erectus* (most notably KNM-ER 730 and 820). However, they did not include iconic African *H. erectus* crania KNM-ER 3733 or 3883 but did include the partial cranium KNM-ER 1805, which is universally otherwise allocated to non-*erectus Homo* (Wood 1991; Leakey et al. 2012). In contrast, in its current usage, most of the additional fossils attributed to *Homo ergaster* are allocated elsewhere to *Homo erectus* (or *Homo* aff. *H. erectus;* Wood 1991). These include the key crania and partial crania from Koobi Fora (e.g., KNM-ER 3733 and 3883), Swartkrans, South Africa (SK 847), and Dmanisi, as well as the mostly complete juvenile skeleton from West Turkana (i.e., Nariokotome boy, KNM-WT 15000), but exclude other African specimens, most notably Olduvai Hominid 9 and Daka.

When so designated, *H. ergaster* differs in several ways from non-*erectus* early *Homo* and *H. erectus* sensu stricto. *Homo ergaster* shows an increase in average brain size relative to the specimens attributed to non-*erectus* early *Homo* (i.e., *Homo habilis*/*Homo rudolfensis*), as well as overall reduction in the size of the face and postcanine teeth. On the other hand, *H. ergaster* has a somewhat smaller average cranial capacity (~800 cc's; range 650–909 cc's; Antón 2003) than does *H. erectus* sensu stricto, and overall the cranium is generally more gracile and the cranial bones are thinner. As discussed below, however, these perceived differences are arguably related to allometric scaling across *H. erectus*. Additionally, *H. ergaster* has been argued to lack pronounced cranial suprastructures such as a well-developed bregmatic eminence, sagittal keel, and angular or occipital torus seen in specimens from Indonesia and China, yet key African specimens such as KNM-ER 3733 and 3883 and the Dmanisi remains express several of these features (Rightmire 1990; Gabunia et al. 2000).

The relatively complete juvenile skeleton of KNM-WT 15000 demonstrates that some individuals were relatively large and may have possessed the long, linear body form associated with tropically adapted recent humans (Ruff and Walker 1993; Graves et al. 2010). However, there is a wide range of body sizes for *Homo ergaster*, including small-sized individuals from Dmanisi, Georgia. For a more complete discussion of postcranial morphology, body size, and range expansion, see the entry on *Homo erectus*.

Key Issues/Current Debates

The key issue for *H. ergaster* is whether the species exists or is a junior synonym of *H. erectus*. The taxonomic debate centers on how to partition the variation seen in a long-lived, globally dispersed fossil species. Several conditions make *Homo ergaster* a problematic taxon. The grounds for allocating the earliest African and Georgian specimens to *H. ergaster* and the Asian remains to *H. erectus* are arguably both geographical and morphological. Several of the African specimens are more gracile than the Asian specimens, in particular possessing thinner cranial vault bones. However, differences in cranial vault thickness and supraorbital toral development have been shown to be the result of allometric scaling of vault thickness with brain size (Antón et al. 2007; Spoor et al. 2007). The purported differences between the African and Asian specimens in the presence of cranial superstructures (i.e., keeling, tori, eminences) also fail to separate the regions as a number of included African specimens (i.e., KNM-ER 3733, 3883, Ileret) express such superstructures (Spoor et al. 2007).

Even among researchers who advocate splitting the African and Asian material, debate exists over which fossils should be allocated to *Homo ergaster*. As mentioned above, the original designation of the taxon included a mixed paratype of non-*erectus* and *H. erectus* specimens from Koobi Fora. More common today is a loose use of the term to refer to all African *H. erectus* specimens as *H. ergaster*. However, this view cannot be supported given that many African specimens (e.g., OH 9, Daka) closely resemble the classical Asian *H. erectus* morphotype (Wood 1994; Asfaw et al. 2002) yet cannot be separated from other African *H. erectus* on the basis of two- or three-dimensional metric analyses (Antón 2003; Spoor et al. 2007; Baab 2008, 2016)

or nonmetric analyses (Rightmire 1990; Antón 2003). Additionally, the inclusion in *H. ergaster* of historically earlier discoveries such as the OH 9 calvaria and the Tighennif (Ternifine) mandibles should give priority to the species for which these specimens serve as holotypes, *H. leakeyi* and *H. mauritanicus*, respectively (Arambourg 1954; Heberer 1963).

Homo habilis

Ronald J. Clarke
Evolutionary Studies Institute, University of the Witwatersrand, Johannesburg, South Africa

Introduction

The species name *Homo habilis* was given by Leakey et al. (1964) to the parietal bones, mandible with dentition (Fig. 1), and hand bones of a juvenile hominid (OH7) that was excavated at site FLK NN1, Olduvai Gorge, Tanzania by Jonathon Leakey on 2 November 1960. It came from a

***Homo habilis*, Fig. 1** OH 7 type mandible of *Homo habilis*, with the right second molar identified and added by R.J.C. (Clarke 2012)

horizon with many broken bones and stone tools of the Oldowan industry dating to 1.8 Ma ago.

From the size of the parietal bones, the child clearly had a brain considerably larger than that of either *Australopithecus* or *Paranthropus*. To Louis Leakey this was the confirmation of his long-held conviction that what he called "a true ancestor of *Homo sapiens*" would be found in the Lower Pleistocene. He had in 1932 proposed that the Kanam mandible fragment from Western Kenya represented such an ancestor. Then, in 1959 he convinced himself that the OH5 *Zinjanthropus* cranium (in reality a massive *Paranthropus*) represented the maker of the Oldowan industry and was in the direct line of our ancestry.

With the 1960 discovery of the large parietals and a mandible with smaller teeth than those of *Zinjanthropus*, Leakey relegated *Zinjanthropus* to a side branch of humanity and embraced the new fossil as the true ancestor of *Homo sapiens* and the maker of the associated Oldowan stone tools. Most of his colleagues were not so readily convinced. Even his collaborator Phillip Tobias, for 3 years after the discovery of the OH 7 fossil, considered that it could be a variant of *Australopithecus*. It was not until the finding of more Olduvai hominids (OH 13, 14, 15, and 16) coupled with his further analysis of the OH 7 fossil that Tobias agreed to join Leakey and hand expert John Napier in naming the new species as *Homo habilis*.

Definition

The name *Homo habilis* had been provided by Raymond Dart at the request of Tobias who was very familiar with Dart's facility with words. *Habilis* meant able, handy, and mentally skillful – an appropriate name for an early large-brained toolmaker. A formal definition of the species is provided in the conclusion.

Historical Background/Key Issues/ Current Debates

Ironically while the additional fossils helped to sway Tobias into recognizing the reality of *Homo habilis*, it was those extra fossils that were to cause confusion and disagreement over exactly what fossils belong to *Homo habilis* and what it represented. While Tobias accepted OH 13 and OH 16 as members of the species, Leakey considered OH 16 to be distinct and called it a protopithecanthropine. This was a reflection of their differing views on the path of human evolution. Tobias saw *Homo habilis* as a stage between *Australopithecus* and *Homo erectus*, but Leakey did not accept *Australopithecus* as ancestral to *Homo* and did not accept *Homo erectus* as a stage between *habilis* and *sapiens*. His view was that *Homo* had a long separate ancestry alongside *Australopithecus* and that *Homo habilis* evolved directly into *Homo sapiens*. He saw *Homo erectus* as a side branch. A detailed assessment of issues relating to the fossils attributed to *Homo habilis* is provided by Clarke (2017), who worked with Leakey and Tobias and has been responsible for the cleaning and reconstruction of many of the fossils that have been attributed to the species then and more recently.

Much later, in 1968, a badly crushed cranium was found by Peter Nzube compacted into a

concretion that had derived from lower Bed 1 at site DK, Olduvai Gorge. The almost unrecognizable hominid was cleaned out of the rock and reconstructed by Clarke. It was immediately accepted by Louis and Mary Leakey, by Phillip Tobias, and currently by most of the palaeoanthropological community as *Homo habilis*. This fossil, known generally as "Twiggy" and with the catalogue number OH 24, was in the words of Tobias (1991) "so fine a specimen of *H. habilis*" that it was given the distinction of being the first-described specimen in his *Homo habilis* volume. OH 24 is often depicted as a classic representative of *Homo habilis*. This is unfortunate because it is actually remarkably similar in cranial morphology to South African *Australopithecus africanus* in the form of Sts 5 and Sts 17. This has been discussed by Clarke (2012) who notes that Leakey et al. (1971) found OH 24 and OH 13 to have morphological differences from the OH 7 type specimen and from OH 16. They said the possibility of taxonomic variation could not be disregarded.

OH 13 is one of the fossils assigned by Leakey, Tobias, and Napier as a paratype of *Homo habilis*. It was found in 1963 by Ndibo Mbuika at site MNK, Olduvai Gorge, and was eroding out of Bed II deposits. It consisted of a fragmentary occipitoparietal region with some temporal fragments and the maxilla and mandible with much of the dentition in place. This had been one of the fossils that helped to convince Tobias that the creation of a new species of *Homo* was justified. The teeth were relatively small with narrowing of the cheek teeth when compared to *Australopithecus*, and the form of the parietals was thought to be humanlike and similar to, though smaller than, OH 7.

Later, Tobias (1971) calculated endocranial capacity for OH 13 on a partial endocast made by Clarke under his direction. Clarke also made comparable partial endocasts of OH 5 *Paranthropus* and Sts 5 *Australopithecus*, both of which had complete endocranial volumes that were known. By making six water displacement volumetric measurements on the partial OH 13, OH 5, and Sts 5 endocasts and comparing them proportionally with the complete endocast volumes, Tobias calculated the endocranial volume of OH 13 at 640 cc and then worked out a projected adult volume of 660 cc.

As this was much larger than the 480 cc he gave for Sts 5 and the 530 cc he gave for OH 5, Tobias thought this confirmed the status of OH 13 as a member of the genus *Homo*. Such a method of calculating brain size is of course prone to much error, and this was well demonstrated when a complete cranium KNM-ER 1813, virtually identical in dentition and cranial morphology to OH 13, produced a complete endocranial volume of only 510 cc (Holloway 2000). This is larger, but not much larger, than the 492 cc upper limit for *A. africanus* tabled by Tobias (1991: 708). As Sts 5 is the only complete, undistorted *A. africanus* braincase known and is a female (Clarke 2013), one should expect possible variation with other members of the species, particularly if such members are from geologically younger sites and separated by great distance geographically.

The KNM-ER 1813 cranium was found by Kimoya Kimeu at East Lake Turkana in 1973. It is dated at nearly 1.9 Ma. Richard Leakey (1974) considered it to belong to *A. africanus* as did Walker (1981), Falk (1986), and Clarke (2012). From this it follows that the virtually identical OH 13 would also belong to *A. africanus* or to a young variant of that species. KNM-ER 1813 was even named as a new species, *Homo microcranous* by Ferguson (1995).

The hand bones associated with the OH 7 mandible and parietals were found to show some features like those of humans which would have facilitated toolmaking. Subsequent finds of hand bones of *Australopithecus*, including the complete hand of StW 573 from Sterkfontein, have shown that such features indicating manual dexterity are not confined to *Homo* but were a general and primitive hominid character associated with probable tree climbing (Clarke 1999).

In 1972 on the east side of Lake Turkana, Bernard Ngeneo found a fossil that would bring new insights to the *Homo habilis* debate (Leakey 1973). Its catalogue number KNM-ER 1470 provided the commonly used name of "1470 Man." It dates to 1.9 Ma, and though reconstructed from

many fragments, it is reasonably complete but lacking tooth crowns. It has a large cranial capacity of 752 cc (Holloway 2000), a prominent upper nasal skeleton, and a broad, flat lower face with widely flaring roots of cheek teeth and indications of relatively large anterior teeth. While Richard Leakey (1973) assigned 1470 to the genus *Homo*, Alan Walker, who had been closely involved in the cleaning, reconstruction and description of the fossil, was inclined to view it as an *Australopithecus* in spite of its large cranial capacity (Walker 1981). Some researchers accepted 1470 as *Homo habilis*, while Bernard Wood (1992), who was very familiar with the Lake Turkana fossils, accepted it as representing a new species, *Homo rudolfensis*. Other specimens from East Lake Turkana that can be assigned to *Homo habilis* are a mandible, KNM-ER 1802, and a partial braincase and dentition, KNM-ER 1590.

Some clarification eventually came in 1995 in the form of a maxilla, OH 65, discovered by Rob Blumenschine and team in an excavation at Naisiusiu in lower Bed 1 of Olduvai Gorge. The maxilla was directly associated with butchered bones and Oldowan stone tools. It was exposed in blocks of tuffaceous and calcareous silty sandstone, which was cleaned from the specimen by R.J. Clarke who then reconstructed the maxilla (Clarke 2012). He could see that it had strong resemblances to KNM-ER 1470 (Blumenschine et al. 2003), but unlike that specimen, it preserved a complete dentition in excellent condition (Fig. 2). It had the same broad, flat lower face (Fig. 3) and the same wide, flaring roots of the cheek teeth. The crowns of these teeth, however, were not correspondingly enlarged but were clearly those of *Homo* and not *Australopithecus* or *Paranthropus*.

It was further pointed out in Blumenschine et al. (2003) and in the OH 65 description by Clarke (2012) that the parietals of 1470 matched in size and shape those of the OH 7 type specimen of *Homo habilis* and thus there is no justification for separating 1470 into a new taxon *Homo rudolfensis*. The fact that the OH 65 maxilla is so obviously that of *Homo* and that it closely matches 1470 reinforces the placement of 1470 as a cranium of *Homo habilis*. At the same time, it adds weight to the argument that the very different maxilla and dentitions of OH 13, OH 24, OH 62, and KNM-ER 1813, coupled with their much smaller brain sizes, suggest they be removed from *Homo habilis* and allied to *A. africanus*. The type mandible of OH 7 *Homo habilis* has the kind of

***Homo habilis*, Fig. 2** OH 65 maxilla of *Homo habilis*

***Homo habilis*, Fig. 3** KNM-ER 1470 cranium (above), compared to OH 65 maxilla (below)

dentition and robustly structured corpus that one might expel to match the dentition and robustly structured lower face of 1470.

OH 16, found in lower Bed II Olduvai by Maiko Matumbo in 1963 after it had been smashed by cattle hooves, would probably have been a complete or nearly complete skull. Several differing reconstructions based on the cranial vault fragments were made by M. Leakey, P. Tobias, and L. Distiller (Tobias 1971). One reconstruction included 107 fragments. However, none of these is conclusive, and there remains the possibility that it originally had a much larger cranial capacity than the 633 cc calculated by Tobias on partial endocasts made by Clarke. Certainly from the dentition, OH 16 could fit with *Homo habilis* as represented by OH 7 and OH 65.

Another badly broken-up Olduvai fossil, a partial skeleton with maxilla, upper dentition, and cranial fragments (OH 62), was found in 1986 (Johanson et al. 1987). The first fragment (part of an ulna) was spotted by Tim White on the eroded surface of Bed 1 deposits close to the FIK *Zinjanthropus* site. More fragments were then picked up by Berhane Asfaw, Don Johanson, and Gen Suwa, and the ensuing careful sieving of the area produced much more. OH 62 was assigned to *Homo habilis*, but it is clear that it aligns with the smaller-brained forms that had been placed in that species rather than with the bigger-brained OH 7 and KNM-ER1470.

Homo habilis of the 1470 kind also lived in South Africa. Clarke (1977) identified as early *Homo* a crushed child cranium, SK 27, from Swartkrans Cave that Broom and Robinson had classed as a large-brained *Paranthropus* with an aberrantly large canine (Fig. 4). Clarke (2017) showed that it was actually a cranium of early *Homo* with a normal sized large brain for that genus and a normal sized canine for early *Homo*, and he found similarities with 1470. He has now also compared the dentition with that of OH 65 and found them to be very similar in tooth sizes and morphology.

Also in South Africa, at Sterkfontein Caves there was excavated a cranium in 1976 that Alan Hughes and Phillip Tobias (1977) believed to be that of *Homo*, largely because of its supposed association with stone tools. However, Ferguson

***Homo habilis*, Fig. 4** SK 27 cranium of *Homo habilis* child from Swartkrans

(1989) demonstrated that it did not differ from *A. africanus*. Kuman and Clarke (2000) showed that it actually came from a separate deposit without stone tools and that morphologically it matched *Australopithecus africanus*. Clarke (2008) has demonstrated that it is in reality the cranium of a male *Australopithecus africanus* very similar to the TM 1511 first adult *Australopithecus* found at Sterkfontein by Robert Broom in 1936.

Conclusion

In terms of chronology, one of the oldest fossils which can be attributed to *Homo habilis* is the maxilla AL 666 (Kimbel et al. 1997) dated to 2.3 Ma from Hadar, Ethiopia, as it has similarity to the OH 65 maxilla. Possibly even older at 2.3–2.5 Ma is a mandible from Uraha in Malawi, originally assigned to *Homo rudolfensis* (Bromage et al. 1995). It is considered here to be *Homo habilis* based on its robusticity and dental

size and morphology, which are similar to the *H. habilis* type specimen OH 7. The species thus extends from about 2.5 to >1.7 Ma (the age of SK 27 at Swartkrans).

It seems possible that *Homo habilis* spread from Africa to the Far East. The *Meganthropus* Sangiran 6 mandible from Java was shown by Tobias and von Koenigswald (1964) to have strong resemblances to OH 7, and there are, from cave sites in China, isolated teeth that are large in comparison to those of *Homo erectus*. There are also intriguing resemblances between some crania from Dmanisi in Georgia and the cranium of 1470.

With the above discussion in mind, *Homo habilis* can be defined as having a large cranial capacity up to 750 cc, more vertical sides to braincase with parietal bosses, a broad frontal bone with widely separated temporal lines, a large face with relatively broad and flat mid and lower face, a prominent nasal skeleton, a broad and deep palate, and a mandible of moderate size but with a robust body.

Homo heidelbergensis

G. Philip Rightmire
Department of Human Evolutionary Biology, Peabody Museum, Harvard University, Cambridge, MA, USA

Introduction

The species name *Homo heidelbergensis* was applied by Otto Schoetensack to a mandible recovered in 1907 at Mauer, near Heidelberg in Germany. Lying in fluvial sands deposited by the Neckar River, the human fossil was accompanied by animal bones indicating an early Middle Pleistocene age. In describing the well-preserved jaw (Fig. 1), Schoetensack (1908) commented on the lack of any bony chin but noted that the teeth are similar in form to those of recent humans. Many years later, F.C. Howell confirmed the presence of primitive features in the specimen while arguing that *H. heidelbergensis* could be distinguished from Asian and African representatives of *H. erectus*. Howell (1960) left open the relationship of the fossil to later Europeans, but *H. heidelbergensis* is now often regarded as ancestral to Neanderthals. It is generally accepted that the jaw from Mauer can be grouped with the mandibles and partial cranium from Arago Cave in France and the cranium from Petralona in Greece. If this grouping is expanded to include the Sima de los Huesos in Spain, then several additional skulls and numerous postcranial bones can be added to the species hypodigm. The Petralona and Arago specimens are also similar in many anatomical respects to crania from sites such as Broken Hill (Kabwe) in Zambia, Elandsfontein in South Africa, and Bodo from the Middle Awash of Ethiopia. Thus, it can be argued that *H. heidelbergensis* inhabited Africa as well as Europe. This species may be related not only to Neanderthals but also to modern humans.

***Homo heidelbergensis*, Fig. 1** The Mauer mandible, considered by Schoetensack (1908) as the type specimen of *H. heidelbergensis*

Definition

Morphology and Evolutionary Significance of *H. heidelbergensis*

Homo heidelbergensis differs from *H. erectus* in brain size. Crania from Petralona, Arago, the Sima, Broken Hill, and Bodo have capacities of 1,100 cm^3 or greater (Holloway et al. 2004), and the average for this group is close to 1,230 cm^3. Height of the cranial vertex is increased in

comparison to *H. erectus*. The frontal region is broader, the outline of the squamous temporal is high and arched as in recent humans, and there is more rounding of the back of the vault. The occipital upper scale substantially exceeds the nuchal plane in length. Morphology of the temporomandibular joint generally resembles that in *H. sapiens*, as is also the case for the tympanic and petrous portions of the temporal bone. In Petralona and other individuals referred to *H. heidelbergensis*, the supraorbital torus is partitioned into medial and lateral segments. Nevertheless, the torus remains very massive. The frontal profile is flattened as in *H. erectus*, and the vault appears less globular relative to that of recent people. There is no reduction in overall face size in relation to *H. erectus*, and the facial skeleton seems to be "hafted" to the braincase in such a way as to accentuate facial projection. Reorientation of the nasal aperture and forward placement of the incisive canal within the palate suggest that the face of *H. heidelbergensis* may be more nearly vertical than is true for *H. erectus* (Rightmire 2008). But only in anatomically modern humans is the face significantly shortened supero-inferiorly and repositioned so as to lie underneath the anterior cranial fossa (Lieberman et al. 2002; Pearson 2008). The mandibular symphysis is receding as in *H. erectus*, and an internal alveolar planum is developed. European jaws referred to *H. heidelbergensis* also display resemblances to Neanderthals (Mounier et al. 2009). Limb bones and a pelvis excavated from the Sima de los Huesos demonstrate that at least some (male?) individuals were tall and robust (Arsuaga et al. 1999), while overall size differences assumed to reflect sexual dimorphism are comparable to those expressed in recent populations.

The place of *H. heidelbergensis* in the human family tree has been the subject of controversy. Dating of the Mauer sands and the mammal teeth contained in these deposits indicates an age of 609,000 years (Wagner et al. 2010). The Mauer mandible is thus one of the oldest fossils from Europe and comparable in age to material from Bodo in Africa. It is likely that populations differing from *H. erectus* evolved very early in the Middle Pleistocene. Just where this speciation event occurred cannot be determined from the evidence available. Whatever the locus, "new" populations must have dispersed quickly through Africa and western Eurasia, and perhaps also into southern Asia. Several evolutionary scenarios have been advanced, and each suggests a different taxonomic interpretation. Bräuer (2008) has grouped Middle and later Pleistocene populations into a series of more archaic and more modern grades within a broad *H. sapiens* category (Fig. 2a). Each grade is defined by advances in brain size and skull form. Although changes to the vault and face accumulate in a mosaic pattern, early and late groups follow one another seamlessly, as segments of a single evolving lineage. Bräuer's scheme recognizing only one species in the later Pleistocene has generally given way to hypotheses emphasizing cladogenesis within *Homo*. Tattersall and Schwartz (2008) and Schwartz and Tattersall (2010) regard living humans as a unique morphological entity, easily separable from most fossil hominins. In their view, *H. sapiens* possesses a package of derived cranial and mandibular features, and individuals that do not share this morphology can confidently be excluded from our species. Thus, multiple distinct taxa should be recognized, and speciation must have occurred repeatedly throughout the Pleistocene. In one such scenario, there are two lineages in addition to *H. erectus* and recent humans (Fig. 2b). A European branch comprising the Neanderthals can be traced back via Petralona, Arago, Sima de los Huesos, and Mauer deeply into the Middle Pleistocene. Proponents of this view (Arsuaga et al. 1997; Hublin 2009) claim that even the oldest European fossils share apomorphies with *H. neanderthalensis* and can reasonably be attributed to this species. A second lineage is rooted in Africa. Specimens including Broken Hill, Elandsfontein, and Bodo are referred to *H. rhodesiensis*, following the nomenclature proposed by Woodward (1921). Some (chronologically late) members of this group exhibit morphology that is archaic, coupled with characters suggestive of a link to anatomically modern humans. Another perspective (Fig. 2c) holds that morphological differences

***Homo heidelbergensis*, Fig. 2** Alternative evolutionary trees showing the relationships of *H. erectus* to Middle Pleistocene hominins, Neanderthals, and recent humans. *Solid bars* depict the duration (first appearance date and last appearance date) estimated for each species. *Broken lines* indicate likely links of ancestors with descendants. In scenario (**a**), mid-Pleistocene and later populations are grouped into a series of grades within a broad *H. sapiens* category. In a second tree (**b**), there are two lineages in addition to *H. erectus* and recent humans. A European branch comprising the Neanderthals can be traced far back into the Middle Pleistocene. Proponents of this view claim that even the oldest European hominins share apomorphies with *H. neanderthalensis* and can be distinguished from a second lineage that is rooted in Africa. The latter is recognized as *H. rhodesiensis*. A third perspective (**c**) holds that morphological differences among the most ancient European and African specimens are minor and can be attributed to geography and intragroup variation. If the Mauer mandible is included within such a broadly construed hypodigm, then the appropriate name for this species is *H. heidelbergensis*

among the most ancient European and African fossils are minor and can be attributed to geography and intragroup variation (Rightmire 2008; Mounier et al. 2009; Stringer 2012). It is argued that all of the hominins should be placed together in one geographically dispersed taxon. The appropriate name for this species is *H. heidelbergensis*.

In summary, the Mauer mandible can be regarded as belonging either to a lineage restricted to Eurasia or to a larger population including representatives from Africa. If the latter, more comprehensive hypodigm is accepted for *H. heidelbergensis*, then this species may be the ancestor to both Neanderthals and anatomically modern *H. sapiens*. Which of these scenarios is to be preferred will be determined by the strength of morphometric similarities linking the European and African remains. The very complete Petralona cranium, for example, is demonstrably like Broken Hill in overall form of the braincase, proportions and massive construction of the upper face and cheek, orientation of the infraorbital region, and several measures of facial projection (Rightmire 2001; Harvati et al. 2010). Such findings support the hypothesis that *H. heidelbergensis* was a widespread (polytypic) species. Later in the Middle Pleistocene, some populations of *H. heidelbergensis* must have moved northward within Europe, where they were subjected repeatedly to episodes of extreme cold. During glacial advances and retreats occurring over several hundred thousand years, these hominins continued to adapt to harsh (cold/dry) conditions. In addition, random drift would have influenced the genetic make up of small or isolated groups. Eventually, such populations evolved the specialized craniofacial characters and (unique) body build of the Neanderthals. During this same time period, other representatives of *H. heidelbergensis* in Africa were becoming more like modern humans. Fossils from Irhoud in Morocco, the Omo KHS locality in southern

Ethiopia, Herto in the Middle Awash region, and Laetoli in Tanzania document this evolutionary progression toward *H. sapiens*.

Current Debates

A differing interpretation arises from ongoing analyses of the discoveries at the Sima de los Huesos. It has been established that the Sima skulls exhibit traits expected to occur (very) early in the evolution of the Neanderthal lineage. As described by Arsuaga et al. (1997), the midface of SH 5 seems to anticipate the distinctive morphology associated with Neanderthals. The infraorbital surface and the side wall of the nose meet at a shallow angle, so as to produce a slight concavity. The cheek region is thus not "inflated" in the extreme manner of Neanderthals, but it can be interpreted as intermediate in form. Also in the Sima sample, continuity of the supraorbital tori at glabella is said to be reminiscent of Neanderthals, and the broad nasal bones are set in a relatively horizontal orientation. At the rear of the cranium, the suprainiac area is large but not very depressed. This trait, and the shape of the occipital torus, may also foreshadow the Neanderthal condition.

Recently, it has been emphasized that the Sima de los Huesos teeth are remarkably like those of "typical" Neanderthals (Martinón-Torres et al. 2012). The upper incisors display conspicuous labial convexity and a distinctive shovel shape, while the upper premolars present a bulging of the buccal aspect of the crown. The M^1s possess an enlarged hypocone, giving the crown a rhomboidal outline characteristic of Neanderthals. The P_3s have a symmetrical contour. Here, the talonid is reduced or absent, so that the remaining cusps occupy a small area near the lingual border of the crown. This Neanderthal-like morphology is more pronounced in the Sima sample than in other Middle Pleistocene hominins. Indeed, Martinón-Torres et al. (2012) claim that the Sima specimens are "more Neanderthal" in form than the Mauer or the Arago dentitions. They suggest that the Sima may constitute a source population for Neanderthals, while Mauer and Arago document the presence of a morphologically distinct lineage. Such a conclusion is favored by Stringer (2012), who envisions two species coexisting in the European Middle Pleistocene. The second species (*H. heidelbergensis*) includes fossils presumed to predate the evolutionary emergence of *H. neanderthalensis*, as well as specimens such as Petralona from later time periods.

Future Directions

Our understanding of human evolution in the Middle Pleistocene remains incomplete. It is likely that additional clues will emerge, as new methods of analysis are applied to the fossils. Also, genomic data are continuing to accumulate, as more detailed DNA sequences are teased from ancient bones and teeth. Already, there are tantalizing indications that a group of archaic hominins related to but genetically distinct from Neanderthals was living in Siberia, several hundred thousand years ago. These "Denisovans" contributed genes to modern Australasian populations (Reich et al. 2010). Integrating the findings from DNA with inferences drawn from the fossil record presents a challenge. Nevertheless, the existence of Denisovans in the Far East can be accommodated by the view that *H. heidelbergensis* was dispersed across Eurasia and into Africa. This morphologically primitive species remains a good candidate for the last common ancestor to both the Neanderthal lineage and modern humans.

Homo neanderthalensis

Rhiannon Margaret Agutter
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

In August 1856, a group of quarry workers exploring the Feldhof caves in the Neanderthal (Neander Valley), Germany, discovered a collection of bones, buried in mud, which they initially assumed to be bear bones. Being quarry workers, and not archaeologists, and believing the bones to be simply animal remains, the men's excavation techniques were far from delicate, and even with encouragement from the quarry owners to recover more bones, only a small number were found – including parts of the arms and legs, ribs, pelvis, and skullcap, many of these fractured (Jordan 1999: 3). Despite the initial identification as non-human, the collection of bones was handed over to grammar school teacher, and Elberfield naturalist's society president, Johann Carl Fuhlrott for further study. Fuhlrott quickly established that the finds were not bear remains but those of an ancient human and in 1857 sent a cast of the cranium to anatomist Hermann Schaaffhausen of Bonn University (Jordan 1999: 11). After further study of all the recovered bones, Schaaffhausen meticulously described the first scientifically recognized Neanderthal, clearly stating his belief that the unusual skull morphology, particularly the pronounced brow ridges, was not due to injury

or disease, but an indication of the discovery of a new species of human. Despite some initial controversy, with several academics claiming the remains belonged to a disfigured and crippled man of various, much more recent, origins, the Neanderthal specimen was finally, and reluctantly, recognized as new, unique species in 1864 and named *Homo neanderthalensis* by William King, Professor of Geology at Queen's College, Galway (Reader 1988: 11). Much of the reluctance to accept the "Neanderthal Man" for what he was came from the lack of facial bones and teeth which would have more firmly identified him as a human ancestor, or as it now appears, a human "cousin" – the product of another branch of human development from our own. It was not long before the required evidence appeared however, with the reemergence of a female specimen found in Gibraltar sometime around 1948 (this "Gibraltar Woman," who's discovery predated "Neanderthal Man's" by approximately 8 years, was actually at least the second Neanderthal discovered and not recognized for what it was; a child's skullcap had been found at Engis in Belgium in 1830 (Jordan 1999: 8–10)) and the discovery of several more individuals in Belgium and France (Reader 1988: 13). Today, *Homo neanderthalensis* has been discovered across Europe and the Middle East, and it has been widely accepted that the "Neanderthal Man" and all the other specimens uncovered belong to their own, unique species. Current debate and research now focuses on whether Neanderthals are genetically related to modern humans, how intelligent they may have been (early descriptions painted them as primitive, brutish creatures, a view which is slowly shifting), how they communicated, whether they possessed any artistic traditions, how they lived, and also how they died.

Definition

Homo neanderthalensis is generally considered to be a separate species of human to *Homo sapiens*, although some scholars argue for a subspecies classification of *Homo sapiens neanderthalensis* (Tattersall and Schwartz 1999: 7117). Neanderthals (also spelled Neandertals without the "h" so as to more clearly represent the German pronunciation), as they are commonly known, likely separated from *Homo sapiens sapiens*, whether on a species or subspecies level, around half a million years ago, becoming geographically isolated, *H. neanderthalensis* developing in Eurasia while *H. sapiens* evolved in Africa (Finlayson 2009: viii). *Homo neanderthalensis* likely became extinct around 30,000 years ago. Recent revision of radiocarbon dates for the Vindija Neanderthals (found in Croatia), some of the youngest known, now place these specimens at approximately 32,000–33,000 ^{14}C years ago (Higham et al. 2006: 553). No Neanderthal fossils dating from later than 30,000 years before present have yet been found, although evidence of fire, butchered animals, and Neanderthal tools have been discovered at Gorham's Cave, in the Rock of Gibraltar dating to 24,000–28,000 years ago, possible evidence of the last of an entire species (Finlayson 2009: 144).

Key Issues/Current Debates/Future Directions/Examples

The Morphology of *Homo neanderthalensis*

The four hundred or so Neanderthal individuals found to date reveal a considerable diversity in morphology, with features varying over geography and time. However, most individuals do show traits relating to the classic Neanderthal type: robust and heavily built with slightly bowed, and proportionally short, limbs; barrel chested, with thick ribs; and broad feet and strong hands with thick, rounded fingers and long thumbs (Jordan 1999: 49–50). However, these postcranial traits can still be seen in some cultures today, especially in Eskimos and other groups who live in cold climates – robustness and shorter limbs are evolutionary adaptations designed to preserve heat – and none of the "typical Neanderthal features" on their own are beyond what could be found in modern humans. Therefore, it is the combination of a number of postcranial and cranial features that help define the species. It is the skulls of Neanderthals that show the distinctive features most

people now associate with *H. neanderthalensis* and those which most differ from our own. The "typical" Neanderthal had a large, thrust forward jaw with big teeth, small or almost nonexistent chin, broad nose, swept back cheek bones, and large pronounced brow ridges over the eyes. His or her skull would also have been longer and flatter than ours with a bun-shaped protuberance at the back (Jordan 1999: 52–54). The Neanderthal skull most likely housed a different shaped and larger brain than the average modern human's (Holloway 1985: 320), ranging from 1,200 to 1,740 ml (with a male average of 1,600 ml and a female average of 1,300 ml) (Jordan 1999: 52). Sexual dimorphism between Neanderthals is represented in both brain size and height (with males standing at around 164–168 cm and females at 152–156 cm (Helmuth 1998: 1)), but *H. neanderthalensis* men and women display a similar pelvis shape (unlike modern humans where male and female pelvises can appear quite different), although the Neanderthal female birth canal is no bigger than a modern woman's (Jordan 1999: 51). Dental growth patterns in Neanderthal children suggest that they developed much faster than *H. sapiens* children although they may have been no bigger at birth (Rozzi and de Castro 2004: 936).

Habitat, Range, and Diet

Although it is theorized that *Homo neanderthalensis* may have diverged from a modern human ancestor as much as half a million years ago, much of the fossil evidence for Neanderthals comes from much later. Most Neanderthal remains have been dated to the time of the last glacial period (around 110,000–10,000 years ago), possibly because shifting glaciers during this period may have destroyed many earlier sites, and it is these individuals that show the most typical Neanderthal features – as discussed above. This is not to say, however, that there is not a range of fossil evidence from prior to this period, but rather that those specimens, while still *H. neanderthalensis*, are of a more generalized type (Jordan 1999: 65). Nevertheless, a picture is painted, in most people's minds, of Neanderthals living in a cold, unforgiving climate in which much of their world was covered in towering glaciers. It is true that many would have lived in an icy Western Europe, but the Neanderthal range was not restricted to glacial areas. In fact evidence has been found of Neanderthals all across Europe and into Central Asia, as far south as the Levant (Jordan 1999: 65), and more recently as far east as Uzbekistan and the Altai region of southern Siberia (Krause et al. 2007: 1). Obviously not all of these places were under ice and snow, but they were impacted by the glacial period – their climates were different from today, some hotter, some colder, and some much drier; their coastlines were different – with much of the ocean bound up in ice sheets, the global sea level was lower, and their flora and fauna was also very different. How Neanderthals exploited this flora and fauna is widely debated. One view of Neanderthals, the one generally most accepted, is of carnivorous apex predators who effectively and selectively hunted a range of animals based on seasonality, the animal's availability, and the hunter's skill (Patou-Mathis 2000: 389). However, some researchers have argued that scavenging and the opportunistic killing of small prey was the Neanderthals most likely subsistence strategy (Henry 2003: 6). In reality, *H. neanderthalensis* probably employed a mix of both selective hunting and the scavenging of recently dead larger animals (Patou-Mathis 2000: 393) as well as the gathering and cooking of plant foods (Henry et al. 2010).

Tools, Art, and Language

Homo neanderthalensis is most commonly associated with the Mousterian culture, a style of stone tools named for the type site of Le Moustier, France (although there are other traditions also linked to Neanderthals such as the Chatelperronian). All Mousterian sites in Eurasia, dating from between 120,000 and 24,000 years ago, which also contain human fossils have been exclusively linked to Neanderthals (Finlayson 2009: 128), and it is the presence of Mousterian tools at Gorham's Cave, Gibraltar, which help define it as one of the, if not the last, sites ever occupied by Neanderthals. The Neanderthals employed a full stone toolkit including points,

scrapers, hand axes, grindstones, and backed knives which were used for butchery, food preparation, and other everyday uses. Some of these tools were hafted and show breakage that is linked with use as projectile points, and a large number show wear consistent with woodworking (Jordan 1999: 84). Wood, generally, does not survive well in archaeological sites, and so it is Neanderthal tools alongside their bones and the remains of their prey which have been used to define their culture. Neanderthal art is practically nonexistent. Unlike their archaic *H. sapiens* contemporaries and successors, Neanderthals did not appear to indulge in elaborate cave painting, nor did they construct statues or figurines. There is some evidence of possibly intentional bone engraving and a few pierced shells and animal teeth have been found associated with Chatelperronian sites (Jordan 1999: 110–111, 213) (which date from around 45,000 to 36,500 years ago (Finlayson 2009: 129), right at the end of the Neanderthal period), but that is about the extent of Neanderthal "art" represented in the archaeological record. It may be, however, that *H. neanderthalensis* expressed his or herself through body painting or the dying of clothes as fragments of iron oxide and manganese dioxide as well as possible ochre grinding stones have been discovered at Neanderthal sites (Jordan 1999: 110). A perceived lack of creative and artistic output by Neanderthals has led people to question how they communicated and whether they had language. Study of *H. neanderthalensis*' skull, jaw, neck, and hyoid suggests that they were capable of speech, if not able to pronounce the full range of sounds that modern humans can (Jordan 1999: 57). It is unknown, however, what form their language, if they had one, took; if they were able to speak in different tenses or with any form of grammar; and whether they possessed the ability to think and express abstract thoughts and feelings and communicate beyond the there and then.

Extinction

Somewhere around 30,000 years ago Neanderthals begin to disappear from the fossil record. Current evidence suggests that the last remaining group of true *Homo neanderthalensis* perished in Gibraltar 24,000–28,000 years ago, but it is, as yet, not definitively proven how or why. Various theories exist as to why Neanderthals suddenly vanished from the archaeological record. Some researchers suggest that *Homo sapiens*, who likely entered Europe around 40,000 years ago and coexisted with Neanderthals for some time, are to blame, either wiping out the Neanderthals through conflict or, less consciously, through the introduction of new parasites or diseases or via competitive exclusion (Banks et al. 2008) where slight advantages on the part of *H. sapiens* allowed them to out-compete Neanderthals for vital resources. The changing climate has also been blamed for Neanderthal extinction – the time they vanish from the archaeological record coincides with the approach of the last glacial maximum, which altered the climate, and ecology, of Europe. It has been suggested that *H. neanderthalensis* simply was not prepared for this change and could not adapt to it as the culturally and technologically superior *H. sapiens* could – Neanderthal hunting and subsistence strategies, living arrangements, and even clothing (Gilligan 2007) may just not have been suitable for the cooling climate. The last major argument for the extinction of the Neanderthals was that they did not go extinct at all but rather interbred with *Homo sapiens*, producing hybrids and passing on genes that remain with us today. Recent genetic evidence suggests that around 2–3% of the genome of modern non-Africans may be attributable to *H. sapiens/H. neanderthalensis* interbreeding (Currat and Excoffier 2011: 15129). This suggests either a low level of interbreeding with a high level of avoidance between the species and/or that the resulting hybrids were evolutionary unfit and mostly unable to successfully pass on their hybridized genes. Either way, it is possible that Neanderthals did not simply "die off" but rather integrated with *H. sapiens*, passed on their genes, albeit probably not very successfully, and still exist in some small way within the DNA of modern non-Africans. Without further archaeological and genetic research, it is impossible to know exactly what happened to *Homo neanderthalensis*. Each theory has its proponents and each has been argued extensively in the

literature; at this point a combination of factors may be the most likely cause for the extinction of the Neanderthals.

Introduction

Homo sapiens is the species commonly referred to as humans. The species evolved in Africa more than 300,000 years ago and is the only living representative of the genus *Homo*. Humans have a gracile body build compared to earlier members

of the genus *Homo*. All humans have a chin and a large brain that is highly developed. This brain allowed for the evolution of behavioral modernity and for continuous social and technological innovations to take place that allow *Homo sapiens* to survive in all habitats.

Definition

Homo sapiens (Linnæus 1758). Species to which all living modern humans belong. While fossils closely resembling living humans are often referred to as "anatomically modern *Homo sapiens*," earlier members of the lineage are sometimes termed "archaic *Homo sapiens*."

Key Issues/Current Debates/Future Directions/Examples

Morphology

Homo sapiens around the world share a number of derived characteristics (Lieberman 2008). These features were not present in previous hominins and include a rounded skull with a high forehead. Also, the browridges are reduced. The face is small, tucked under the forehead, and characterized by the presence of a mental protuberance or a forward projecting chin. The anterior teeth are small, indicating that they were less used as tools and that food was alternatively softened by processing such as grinding and cooking. The brain has a mean cranial capacity of about 1350 cc. This value is comparable with that of *Homo neanderthalensis* but is larger, relative to body size. The postcranial skeleton of *Homo sapiens* is more gracile than that of previous hominins. The earliest humans were more robustly built than people today because of their high level of daily activities, but in general, there was a tendency even in early *Homo sapiens* to have thinner walled long bones and more lightly built hands and feet. The scapula (shoulder blade) is less muscular and the pelvis is less robust, with a shorter pubic area. The skeletons of the earliest modern humans displayed long limbs and short trunks, reflecting the warm African climate in which they evolved (Holliday 1997). More recent humans show adaptation to the environment in which they live.

Key Fossils

The first widely accepted ancient *Homo sapiens* fossils were discovered in the Cro-Magnon rockshelter in Les Eyzies-de-Tayac, France (Fig. 1). The human remains at the site represented at least five people. The associated fauna and Upper Paleolithic archaeology confirmed that these fossils were very ancient. The site gave its name to European early modern humans in the Old Stone Age: the Cro-Magnon people. Not long after this discovery, more sites were uncovered across Europe, showing that humans had occupied Europe from at least 35,000 years ago, while recent re-dating of specimens from Italy and the UK indicates that they may have been present in Europe as early as 43,000 years ago (Benazzi et al. 2011; Higham et al. 2011).

The African continent has yielded the oldest *Homo sapiens* skeletons that include modern human-derived characteristics. The most securely dated of these are two partial skulls from Herto, in Ethiopia's Middle Awash River Valley. They date to between 160,000 and 154,000 years and show a humanlike cranial capacity, a tall forehead and rounded braincase of the skull, with a small, non-projecting face. There is earlier evidence from Omo Kibish (Fleagle et al. 2008) at 195,000 years, and this includes two partial skulls and some postcranial material. The first skull Omo 1 shows the most modern features, but Omo 2 is much more archaic, and additional newly excavated fossils have also displayed this mixed morphology (Fig. 2). In 2017, new thermoluminescence and ESR dates were announced for the site of Jebel Irhoud, Morocco. The Middle Stone Age cranial material shows clear *Homo sapiens* characteristics in its facial, mandibular, and dental morphology while retaining a more primitive neurocranial and endocranial morphology. The mosaic of modern and primitive features present around 315 ± 34 thousand years ago indicates an early phase of *Homo sapiens* evolution in Northwest Africa (Hublin et al. 2017).

Life History

Modern humans have distinctive growth and development patterns. These are different from those of our living primate relatives. Through the study of perikymata in teeth (incremental growth lines), it became clear that modern humans grow up slower than do our living primate and fossil hominin relatives. This slow growth is due to a long period of childhood growth and dependency. The extended childhood allows children to develop linguistic and other complex cultural skills that other primates do not have and,

arguably, skills that earlier fossil hominins did not possess (Smith et al. 2010). In addition to extended childhood, modern humans often live post-reproductively, indicating that the elderly in society still have a crucial role to play. This extended life span has been suggested to be linked to the importance of intergenerational transfer of cultural information. Even though older members of the population no longer play an active role in reproduction and hunting, they can collect resources more locally and provide knowledge and skill to the younger generations.

Genetics

Before the development of genetics, *Homo sapiens* was distinguished from earlier hominins primarily using morphology. Fossils and associated archaeology were the only sources of evidence to uncover the evolutionary past of humans. Advances in molecular genetics now not only allow scientists to look at how humans differ genetically from other living primates, but ancient DNA (aDNA) analysis of fossil material and genetic patterning in modern humans elucidate the origins and diversification of *Homo sapiens*.

Initially, analysis of modern human and chimpanzee DNA was compared (The Chimpanzee Sequencing and Analysis Consortium 2005) and found to differ in around 1.06% of the nucleotides. Insertions and deletions in parts of the DNA account for another 3% of the difference between the genomes. Nevertheless, phenotypically, there is a big difference between chimpanzees and humans, and this is because of the different ways in which similar genes express themselves in humans and in chimpanzees. This demonstrates clearly that the number of mutations in protein coding genes is not necessarily proportional to the phenotypic expression.

Recent developments in the successful extraction of DNA from fossil hominins have created a whole new area of research on ancient DNA. Several Neanderthal mitochondrial and nuclear DNA sequences, as well as Denisovan DNA, are currently being compared and are helping paleoanthropologists to determine what makes *Homo sapiens* genetically and, thus, physically. As geneticists further unravel the genome of humans and living primates and study the phenotypic expression of individual genes, it will be possible to reconstruct phenotypic differences between earlier hominins and *Homo sapiens* more accurately than is possible from the fossil and archaeological record alone.

Modern Human Behavior

For over a million years, *Homo erectus* and the subsequent species *Homo heidelbergensis* used Acheulean tools through most of western Eurasia and Africa. These tools proved advanced enough to allow the survival of the hominins using them over a wide range of habitats. With more complex technology and specialized tools, *Homo sapiens* has gradually been able to adapt to an even wider range of environments. In addition, *Homo sapiens* also show a range of other behaviors not seen in other living and fossil species: elaborate symbolic, artistic, and religious behaviors as well as advanced problem-solving. These are the result of our cognitive abilities and our cumulative and complex learning strategies.

Until fairly recently, many workers believed that modern human behavior had evolved rapidly in Europe some thousands of years after anatomically modern humans had originated in Africa. Anthropologists believed the presence of cave paintings in Europe, the use of symbolism, the diversification of hunting techniques and technology, the inclusion of aquatic resources in the diet, and a wider use of raw materials provided the essentials for behavioral modernity. Recent discoveries and a more comprehensive interpretation of what makes up modern behavior have now shown that human behavioral modernity did not evolve suddenly in Europe. Instead, it accumulated more episodically in Africa during the Middle Stone Age and reached the essentials of modernity before modern humans spread out of Africa around 60,000 years ago (McBrearty & Brooks 2000).

Some of the earliest potential evidence for modern behavior comes from sediments dated to about 164,000 years at the Pinnacle Point caves, South Africa, in the form of stone bladelets, ground red pigment, and the cooked remains of shells such as mussels and abalone (Gibbons

2007). Other evidence for the use of aquatic resources comes from Katanda (Congo) where bone harpoons were found and the remains of catfish dating back to about 90,000 years (McBrearty and Brooks 2000). Also at Blombos Cave in South Africa, bone points have been found, with evidence for pressure flaking in the Middle Stone Age Stillbay industry, well before these are widespread across Europe. Composite tools were also included in tool assemblages during the Middle Stone Age in Sudan, and there is clear evidence that raw materials were transported over extended distances. At Mumbwa Cave in Zambia, there is early evidence for the construction of shelters, and many sites have yielded remnants of hearths.

There is also evidence for decorative non-utilitarian objects in the form of *Nassarius* shell beads, with the oldest currently documented at Skhul and Qafzeh Caves in Israel and Taforalt Cave in Morocco, at about 100,000 years. The shells are perforated in the same way, and some show signs of ochre treatment. These are also known from sites such as Blombos Cave in South Africa at a somewhat later date. Ostrich egg shell beads are a little younger than shell beads but are evident before *Homo sapiens* left Africa about 60,000 years ago. Red ochre use seems widespread from at least 150,000 years ago, with ochre applied to artifacts and engraved pieces dating back to about 100,000 years. In 2011 (Henshilwood et al. 2011), what appear to be red ochre paint kits from Blombos Cave were published, also dating to about 100,000 years ago. Evidence of the first ritual burials is known from about 110,000 years ago at Skhul and Qafzeh Caves in Israel. However, so far, there is only disputed evidence for figurative art older than about 45,000 years ago, as modern humans spread from Africa into the rest of the world.

The slow accumulation of modern human behavior in Africa despite clear evidence for full anatomical modernity around 195,000 years ago can be explained by the gradual technical advances during the Middle Stone Age that slowly gave rise to larger and more networked populations. Increased group size would have facilitated the spread and growth of technological innovations, and extended social networks would have positively affected food acquisition efficiency, leading in turn to surpluses, role specialization, increased symbolic and linguistic expression, and ritual activity. Although some authors (Klein 2009) argue that these changes were associated with possible brain mutations, we see similar rapid accelerations in cultural and technological advances without these mutations throughout human history (e.g., the Neolithic and Industrial Revolutions).

Honey Bee: Management

Kathleen A. Dogantzis[1], Brock A. Harpur[2] and Amro Zayed[1]
[1]Department of Biology, York University, Toronto, ON, Canada
[2]Department of Molecular Genetics, University of Toronto, Toronto, Canada

The relationship between humans and honey bees (genus *Apis*) spans centuries (Crane 1983). Honey bees consist of between 10 and 12 extant species predominantly located in Asia (Ruttner 1988). Fossil evidence suggests that honey bees originated during the Oligocene, between 30 and 20 million years ago (Engel 1998; Kotthoff et al. 2013). *A. mellifera,* referred to as the European honey bee, is the most well-known and intensively managed bee. *A. mellifera* is native to Africa, Asia, and Europe, but because of human-mediated dispersal, is now found on all continents except Antarctica.

Humans have most likely been foraging for honey since the dawn of their evolution. The earliest evidence of honey hunting – the process of destructively acquiring honey from wild colonies – was depicted in cave paintings found in Northern Spain (likely between 30,000 and 9000 BC) (Crane 1983). Evidence of honey hunting was also documented in cave painting found in Eastern Spain, dated between 8000 and 2000 BC. There is extensive evidence of honey hunting in Africa from numerous depictions in rock paintings, but such paintings are difficult to date reliably (Crane 1983). As well, evidence of pottery shards containing honeybee products within Northern Africa, Anatolia, and Central Europe from at least 9000 years ago–associated with the earliest instances of farming in the area–suggest a long history of association of humans and honeybees and potentially of active beekeeping (Roffet-Salque et al. 2015).

The first archaeological evidence of beekeeping – the propagation of honey bee colonies by humans – is found in scenic depictions from Ancient Egypt around 2400 BC (Crane 1983;

Kritsky 2015). Depictions from the sun temple of Nyuserre Ini, Pharaoh of the Fifth Dynasty during the Old Kingdom, illustrate men pouring honey into pots, accompanied by hieroglyphs depicting a bee – *bit* (Kritsky 2015). The oldest discovered apiary was found in Tel Rehov, an archeological site in the Jordan Valley, dated to be 3000 years old. The honey bees preserved in the Tel Rehov apiary are different from contemporary honey bee subspecies inhabiting the Jordon Valley, which suggests that beekeepers were already importing bees and managing large apiaries during Biblical times (Bloch et al. 2010).

Older techniques of collecting and storing colonies in pots rendered inspecting a colony and extracting honey in a noninvasive manner very difficult (Crane 1983). With the advent of selectively removing honeycomb on pieces of wooden frames, beekeepers were able to nondestructively harvest honey and see the inner workings of the hive (Kritsky 2010). The first instance of moveable frames came from Greece in 1682, and these would be the predecessors of today's modern Langstroth hive, which was invented in 1852 (Crane 1983; Kritsky 2010). The Langstroth hive allowed beekeepers full access and control of honey bee colonies and spurred the development of commercial beekeeping around the globe (Crane 1983; Kritsky 2010).

Native *A. mellifera* subspecies – at least 26 subspecies – are organized into at least four evolutionary lineages or groups found in Africa, Western and Northern Europe, Eastern Europe, and the Middle East (Ruttner 1988; Garnery et al. 1992; Arias and Sheppard 1996; Franck et al. 2001; Whitfield et al. 2006; Wallberg et al. 2014; Cridland et al. 2017), with a potential fifth lineage recently identified in Northeast Africa and parts of the Middle East (Franck et al. 2001; Cridland et al. 2017; Harpur et al. 2014). The biogeographic and evolutionary history of the European honey bee is – like humans – both complex and intriguing. The history of *Apis mellifera* is best studied by examining differences in the genetic makeup of bees across the globe. Recent genetic studies have shown that the European honey bee originated in either Africa (Whitfield et al. 2006; Cridland et al. 2017) or Asia (Han et al. 2012; Chen et al. 2016; Wallberg et al. 2014) and then colonized Europe via at least two independent expansions. One of the colonization routes spans through Africa and into Europe through the Iberian Peninsula, while the second follows an Eastern route through Asia into Europe. The timing of these expansions is hypothesized to have begun 0.3–1.3 million years ago (Cornuet and Garnery 1991; Arias and Sheppard 1996; Wallberg et al. 2014; Chen et al. 2016).

The long history of human and honey bee interactions has had a profound influence on the bee's contemporary geographic distribution. European honey bees were introduced to the New World by means of European settlers as early as the seventeenth century (Ruttner 1988; Sheppard 1989). Subsequent introductions from Europe brought a mix of different European honey bee subspecies, including *A. m. mellifera*, *A. m. carnica* and *A. m. ligustica* (Sheppard 1989). European honey bees thereby spread through North and South America via beekeeping activities and natural dispersal. A more recent introduction of the African subspecie *A. m. scutellata* to Brazil in 1956 led to the invasion of Africanized – so-called killer – bees (Kerr 1967). Currently, Africanized bees are found in North America in the southern and southwestern United States, to as far south as Argentina in South America.

The movement of honey bees has led to commercial populations with a great deal of genetic admixture – or mixed ancestry – which results from intentional or natural hybridization events between subspecies from West Europe and East Europe (Harpur et al. 2012, 2015; Whitfield et al. 2006). This genetic admixture is readily explained considering beekeeping practices such as international importation of honey bee queens, as well as by the honey bee's mating biology: queens naturally mate with 15 to 20 different males from a relatively large geographic area, which promotes outbreeding and genetic mixing. As a result of mixing, managed honey bees actually have higher genetic diversity than their progenitors in East and West Europe (Harpur et al. 2012).

Today, honey bees are responsible for a large portion of crop pollination, accounting for at least 34% of pollination services in the United

Kingdom (Breeze et al. 2011) and likely more in North America. No single insect pollinates more plant species than the honey bee (Breeze et al. 2011). Honey bees are used to pollinate fruit crops (apples, apricots, avocados, blueberries), oilseeds (cotton, flax, soy), forage and legume crops (alfalfa, clover, buckwheat), and vegetables (broccoli, beans, cucumbers, carrots, peppers). Though the traditional honey harvesting and collecting methods still persist today, the contemporary relationship between humans and honey bees has expanded to a global multibillion-dollar industry.

Hopewell Culture, Archaeology of the

Bradley T. Lepper
Archaeology and Natural History Unit, Ohio History Connection, Columbus, OH, USA

Introduction

The Hopewell culture, named for the Hopewell Mound Group in the Paint Creek valley of southern Ohio, is best known for its monumental earthworks and the broad range of exotic raw materials its artisans acquired and crafted into magnificent works of art (Fig. 1). The Hopewell culture reached its fullest expression in the valleys of the major streams that flowed southward into the Ohio River in southern Ohio and neighboring Indiana during the Middle Woodland period (100 BCE–500 CE). Hopewell-related manifestations, however, are known throughout eastern North America, from the Mississippi River to the western flanks of the Appalachian Mountains and from the southern Great Lakes to the Gulf of Mexico.

Hopewell Culture, Archaeology of the, Fig. 1 Hopewell copper face effigy from the Hopewell Mound Group (A283/000140). 6.25 mm high. Ohio History Connection

The Hopewell culture was an outgrowth of the earlier Adena culture in the Ohio Valley. The Hopewell people built upon the foundation of mortuary ceremonialism centered on mound-building and the acquisition of exotic raw materials established during the Early Woodland period (800–100 BCE). The reasons for this florescence are unclear, but it appears to have been rapid and is not obviously due either to demographic or ecological causes (Carr and Case 2005: 290).

Definition

The Hopewell culture represents a brilliant florescence of art, architecture, ceremony, and interregional interaction that was unparalleled in North America up to that time (Fig. 2). It encompassed a number of societies in eastern North America linked by an intense focus on mortuary ceremonialism performed in monumental architectural settings and participation in an exchange network that likely involved a mixture of gift-giving, pilgrimage offerings, the direct acquisition of exotic materials through extraordinary journeys by individuals and small groups, and trade.

Typical artifacts that appear to have reflected a Hopewell identity included earspools and breastplates made from copper, elegant mica cutouts, marine shell vessels, animal effigy platform pipes, frequently oversized spear points and knives made from obsidian, and cores and bladelets made from both Flint Ridge flint and Wyandotte chert (Seeman 2004).

Hopewell farmers cultivated the plants of the Eastern Agricultural Complex, including goosefoot, knotweed, and maygrass, with their starchy seeds rich in carbohydrates, sunflower with its oily seeds, and sumpweed, as well as tobacco. In spite of this evidence for horticulture, Hopewell people appear to have relied principally on hunting, gathering, and fishing for their livelihoods. The cultivated plants provided both a storable

surplus of comestibles that would have alleviated seasonal food shortages and food to help support the periodic large gatherings at major earthwork centers.

The most important ceremonial earthwork centers include the Hopewell Mound Group, Mound City, Seip Earthworks, and the Portsmouth Earthworks in the Scioto River drainage; the Newark and Marietta earthworks in the Muskingum River drainage; Fort Ancient and the Turner Earthworks in the Little Miami Valley; and the Mann Site and Mount Vernon Mound in the Wabash Valley in Indiana.

The Newark Earthworks is the preeminent example of geometric earthworks consisting of two large circular enclosures, a square, and an octagonal enclosure all connected by avenues framed by parallel walls with the entire complex spreading across more than 1,000 ha (Lepper 2004). The Fort Ancient Earthworks is the largest hilltop enclosure in the Hopewell world. More than 5 km of earthen walls surround a mesa top overlooking the Little Miami Valley. In spite of its name, it does not appear ever to have functioned as a fortification. Instead, it appears to have been a ceremonial center very like the large geometric earthworks, but with less of an emphasis on mortuary activity.

The ceremonial nature of the Hopewell earthworks is indicated by a number of factors, including a focus on mortuary ceremonialism, the frequent incorporation of cryptic astronomical alignments into the architecture (Fig. 3), and the general absence of significant residential sites at the earthworks. Many earthworks do have

Hopewell Culture, Archaeology of the, Fig. 3 Moonrise over the Octagon Earthworks at Newark, Ohio. CERHAS, University of Cincinnati

domestic sites in association, but these plausibly have been interpreted as the temporary encampments of largely nonresident visitors, such as pilgrims coming to the site to participate in ceremonial activities.

Although earthworks dominate our view of the Hopewellian ceremonial landscape, it is increasingly clear that originally these sites included a significant number of wooden structures, including Big Houses (often characterized as charnel houses) and woodhenges. The woodhenge at the Stubbs Earthworks, for example, consisted of 172 wooden posts configured in a nearly perfect circle 73 m in diameter (Cowan 2005: 148). The Moorehead Circle at the Fort Ancient Earthworks was a series of three concentric rings of wooden posts surrounding an area of intense ritual activity, including limestone pavements, a centrally located large, shallow basin filled with bright reddish soil, and an activity area characterized by a succession of superimposed floors (Riordan 2015).

Key Issues

An important unresolved question is the nature of Hopewellian domestic sites, which occur in proximity to the earthworks as well as in widely dispersed locations in the surrounding valleys and uplands. There is disagreement among Hopewell researchers as to whether these settlements were sedentary homesteads of dedicated farmers or hamlets occupied seasonally by mobile foragers (Dancey and Pacheco 1997; Yerkes 2002). Excavations at the Patton site in southeastern Ohio revealed the remains of a substantial rectangular structure of wattle and daub suggesting to the investigators a commitment to some degree of permanence at least at this site (Weaver et al. 2011).

The most striking aspect of the Hopewell culture is the impressively large ceremonial earthen architecture (Fig. 4), including geometric enclosures, hilltop enclosures, and mounds in a variety of shapes and sizes. The scale of these ceremonial landscapes is far grander than would be needed to serve the needs of the local population who lived in the small, dispersed domestic sites. Therefore, the earthworks must have been locations of periodic large gatherings. Perhaps the most fascinating set of issues raised by the monumental architecture and its associated far flung interaction sphere (Fig. 5) is that they were created and operated by largely egalitarian societies that did not coalesce into a hierarchically organized polity.

The nature of Hopewell society and the purpose of the large ceremonial centers is the focus of ongoing debate. The most widely accepted model of Hopewell social organization is the Vacant Center/Dispersed Hamlet model (Dancey and Pacheco 1997). In this model, the earthworks are the ceremonial centers for a territorial proto-polity of related small hamlets in a sort of orbit around a centrally located earthwork. Alliances of these proto-polities are expressed in larger earthworks possibly located at territorial junctures at which joint funerary ceremonies helped to solidify the alliance (Carr and Case 2005). Byers (2011) presents an alternative model in which the networks of Hopewell hamlets were not territorial and the earthworks were built by sodalities, that is, groups bound by ties of companionship instead of kinship. For Byers, the mortuary foci at the earthworks were not kinship-based cemeteries, but the result of complex world renewal rituals in which human remains served as the principal sacrificial offerings.

There is no general agreement on the factors responsible for the dramatic rise and precipitous decline, sometimes characterized as a true collapse, of the Hopewell culture. Case and Carr (2008) convincingly argue that neither the florescence nor the dimming of Hopewell culture can be linked to demographic or ecological causes and that particular, historical events of a spiritual-religious nature likely initiated both.

Alternatively, the collapse of the Hopewell culture may be related to increasing competition between communities for scarce resources. Certainly, the achievements of the Hopewell culture were tied to a network of peaceful cooperation, sometimes referred to as the *Pax Hopewelliana*, and the subsequent Late Woodland period (CE 500–900) witnessed a shift toward population

Hopewell Culture, Archaeology of the, Fig. 4 Map of a section of 12 miles of the Scioto Valley with its ancient monuments. Ephraim Squier and Edwin Davis from the first publication of the Smithsonian Institution

aggregation into larger villages frequently situated in defensible locations and with palisades, earthen walls, or ditches surrounding the settlements. In addition, Late Woodland and Late Prehistoric (CE 900–1650) human remains recovered from burials frequently exhibit traumatic injuries, including projectile points lodged in skeletons, whereas there is little or no evidence of

Hopewell Culture, Archaeology of the, Fig. 5 Map showing the extent of the Hopewell interaction sphere. Ohio History Connection

such interpersonal conflict in any Hopewell human remains (Case and Carr 2008: 650–1).

Horning, Audrey

Katherine Fennelly
Department of Archaeology, University of Manchester, Manchester, UK

Basic Biographical Information

Audrey Horning earned her B.A. at the College of William and Mary in Williamsburg, Virginia, and completed her M.A. in 1991 and her Ph.D. in 1995, both at the University of Pennsylvania. Her doctoral thesis focused on comparative analysis of colonial Jamestown, the first English colony in Virginia. Horning previously lectured in historical archaeology and colonialism at the University of Leicester. Prior to this, she was Assistant Professor of Anthropology at the College of William and Mary. She also worked as an archaeologist for the Colonial Williamsburg Foundation and directed excavations at Jamestown.

In 2001 she received the John L. Cotter Award (Society for Historical Archaeology) for her outstanding contributions as a young historical archaeologist, as recognition for her doctoral dissertation on seventeenth-century Jamestown and a study of the "mountain folk" of Appalachia. Horning has recently been hosted as a visiting scholar at St. Mary's College, Maryland, in 2010, and at the University of Denver in 2011.

Horning's work is primarily concerned with colonialism, identity, and the North Atlantic world from the seventeenth century to the present day. She currently teaches and conducts research at Queen's University Belfast. She is a fellow of the Society of Antiquaries of London and Associate Editor of Historical Archaeology journal. Horning is an active member of the Irish Post-Medieval Archaeology Group, and edits the newsletter, and of the Society for Post-Medieval Archaeology, of which she is secretary.

Major Accomplishments

Reassessment and realignment of early colonial sites within a broader North Atlantic context has been a central focus of Horning's research, notably at Jamestown (2006). She has brought this approach to postmedieval archaeology in the British Isles. Horning's work in Ireland has centered on the study of rural sites, notably excavations at Achill Island on the west coast and at rural sites in Northern Ireland. Inferences drawn from these excavations have addressed the problematic nature of the presentation of identity through material culture (Horning 2000, 2001, 2007). Similarly, investigations at rural sites in the reforested region of Shenandoah National Park, Virginia (Horning 2000), formerly a working agricultural and small-scale industrial landscape, have focused on the displacement of people and the appropriation of identity. This forms part of Horning's broader research the role of historical archaeology in reassessing accepted historical identities.

In her work on historical identities, Horning has examined material culture of rural identity in Ireland in a museum context. Her research on museum collections has illustrated a stark contrast between the prominence of "authentic" Irish wares in museums and the substantial volume of imported goods such as tea cups evidenced by fragments uncovered during excavations (Horning 2007). This is comparable with her work on the people of Shenandoah. In the context of early twentieth-century land clearance at Shenandoah, the public image of the local people as cultural backwards was countered by the discovery of artifacts like a toy ray gun at one of the rural

sites, among other contemporaneous artifacts (Horning 2005). Central to Horning's thesis is that the creation of an "authentic" ideal has been used in the past as a motive for displacement; she also asserts that "authenticity" has been used as a vehicle for nationalism in postcolonial Ireland.

Horning's most recent publications have been concerned with the re-situation of Ireland within a broader North Atlantic context, both as a colonial enterprise and a market for the consumption of colonial goods (Horning et al. 2007; Horning and Palmer 2009; Horning and Brannon 2009). She has focused on the early plantation period in Ireland and earlier, drawing inferences from the remains of medieval village sites on the relationship between English settlers and native Irish in Anglo-Norman Ireland (2012). She has written extensively on the future of historical archaeology and has promoted the practice of postmedieval archaeology in Ireland (Horning et al. 2007; Horning and Brannon 2009).

Horse Gram: Origins and Development

Eleanor Kingwell-Banham and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Horse gram (*Macrotyloma uniflorum* (Lam.) Verdc. (syn. *Dolichos uniflorus* Lam.)), also known as *kulthi, gahat, Madras gram, grain de cheval, kerdekorn*, and *favalinha*, is a domesticated bean grown today across tropical Africa, South Asia, Southeast Asia, China, and Australia. In much of the older literature on the botany and archaeology of India, it is referred to as *Dolichos biflorus*, although this is a misnomer, and accepted nomenclature today is *Macrotyloma uniflorum* (see Smartt 1990; Fuller 2002). The stems and leaves of the plant are often used as fodder, while the beans are harvested for human consumption. Horse gram is tolerant of both drought and low soil fertility, making it a particularly important crop in drier areas of south India (Kachroo and Arif 1970; Smartt 1990). It requires very little input and can be used as a green manure to improve depleted soils. As such, it is often an important component of crop rotation systems in which it is usually planted on fallow fields. It can be successfully intercropped with cereals, including pearl millet, sorghum, and the small millets. In addition, it does well as an understory crop in orchards and plantations.

Horse gram is a drought-resistant crop largely grown in areas with less than 900 mm annual rainfall, though it can be grown with as little as 380 mm. While it can tolerate higher temperatures, ideal temperatures for growth range between 25 °C and 35 °C. As such it is particularly suited to tropical environments. It takes around 120–180 days to reach maturity. Horse gram is easily harvested by uprooting. Because of this a relatively high number of weeds may be incorporated into the crop, increasing the prevalence of weed seeds in assemblages from each stage of processing and potentially increasing the visibility of horse gram crop processing in the archaeological record. It is processed in a similar way to glume-wheats, with two episodes of threshing and winnowing (Fuller and Harvey 2006). The second episode may occur daily, with the day's quota of the pulse removed from storage and prepared separately. This method increases the chance of archaeological preservation and may bias towards the prevalence of this crop in the archaeological record. The beans are usually dried for storage and longevity. These dry beans tend to be soaked overnight prior to cooking. Boiling is most common; however, they can also be fried or roasted. Boiling produces both cooked beans, which may be fed to humans or livestock,

and horse gram water, which can be condensed to produce a thick protein rich stock for soups and broths. In addition, the beans can be sprouted prior to cooking. There are several claimed health benefits and medicinal properties to horse gram, including its diuretic effect which may help kidney stones.

Major Domestication Traits

The identification of horse gram is relatively straightforward, although there is quite a lot of variability in both modern and archaeological populations. The beans of horse gram are generally around 5 mm in length when mature, are trapezoidal, and tend to be slightly reniform (Fig. 1). The hilum can be found within a depression at the center of the bean's edge. When the bean is split, the embryo can be seen to be around a third of the length of the bean and roughly parallel to the base of the seed.

The wild progenitor of horse gram is not well studied; however, archaeobotanical and ecological evidence indicates that it is a domesticate of India (Fig. 2). Wild populations are found across India within dry tropical evergreen and savannah vegetation zones (Jansen 1989; Asouti and Fuller 2008). From c. 2500 BCE there is evidence for horse gram stretching from southern to northwestern India (the state of Haryana), and this could imply that it was brought into cultivation more than once. The Haryana region, the Gujarat region, and the south Deccan are all plausible foci or early cultivation or domestication. Wild populations of horse gram are also found in Africa; however, there is no evidence to indicate that these were ever brought into cultivation there.

Horse Gram: Origins and Development, Fig. 1 Sketch of *Macrotyloma uniflorum* seed, from side view, hilum view, and interior of split cotyledon

Timing and Tracking Domestication

The high ubiquity of this crop at Neolithic southern Indian sites c. 2000 BCE suggests that it was a staple food. Furthermore, early finds indicate that it was part of an indigenous south Neolithic crop package along with two millets (*Brachiaria ramosa* and *Setaria verticillata*) and another pulse (*Vigna radiata*) (Fuller et al. 2004). This crop package appears to be synonymous with the semi-pastoral Ashmound culture, in which large areas of accumulated burnt cattle dung and hilltop settlements are prime features. It appears to be a later introduction to the agriculture in the Ganges plains and eastern India (Orissa) in the Chalcolithic after c. 1500 BCE. In the period 400–100 BCE, horse gram is found on the Malay peninsula in southern Thailand, for example, at Khao Sam Kaeo, where it might have been imported with other Indian pulses for Indian enclaves at important craft and trading cities (Castillo and Fuller 2010). Today it is not cultivated for human consumption in Southeast Asia, and this crop has remained restricted to South Asia, mainly as a low-status pulse.

Horse Gram: Origins and Development,
Fig. 2 Map of wild South Asian horse gram and distribution of early archaeological finds. Modern documented wild populations are few, but it is inferred that they should have been wild spread in the dry savannah zone (shaded) and possibly more sporadically through areas enclosed in dashed lines. This map has been modified from Fuller and Harvey (2006) and updated

Colt: male juvenile horse

Horses belong to the genus *Equus*, family Equidae in the order Perissodactyla (odd-toed hoofed mammals). Domestic horses are derived from the wild horse *Equus ferus* which was widespread across Eurasia and North America in the late Pleistocene but went extinct across nearly all of that range in the early to mid Holocene. The tarpan may have been a remnant population on the wild horse in Europe; the last individual died in captivity in the early twentieth century. The highly endangered Przewalski's horse, which historically went extinct in the wild but survived in zoological collections, may also be a remnant of this wild progenitor species. Although recent genomic analyses suggest that this horse has interbred with domestic horses (Der Sarkissian et al. 2015), it is even possible that it derives from animals that went feral very early in the domestication process (Gaunitz et al. 2018). However this horse has a different chromosome number and paternal and maternal lineages that are not present among modern horses, together with genome-wide differentiation, so it represents a separate lineage.

There are currently several free-ranging populations of horses in Eurasia, Africa, and the Americas. They are commonly referred to as wild horses, especially in North America (where they are also called mustangs). All these populations are actually feral, that is, descendants of domestic animals that are now free ranging.

Contrary to what seems to have occurred in many domesticates, no obvious osteological characteristics can be used to separate the first domestic horses from their wild counterparts. This has made it quite difficult to identify early domestic horses in the archaeological record. The earliest remains have most often been identified on the basis of tooth wear that could be indicative of wearing a bit or cribbing, changes in frequency of remains at individual sites, proportion of remains from the different age and sex groups, or remains of ritually sacrificed horses (Olsen 2006). The examination of abnormalities on the skulls of some ancient horses suggested that they wore a bit, and isotope analyses of food remnants on pottery shards revealed the presence of horse milk. These two pieces of evidence indicate that a population of central Asian horses was domesticated by 5500 years ago (Outram et al. 2009). This may be close to the time and place of domestication and shows that at this early point in their domestication, they were used both as a food resource and for transport.

The mode of domestication in horses was likely unique. Horses were the last of the common farm animals to be domesticated, thousands of years after dogs, cattle, pigs, goats, and sheep, and when these species were already spread across continents. Consequently, it would seem that there was no obvious need for the domestication and expansion throughout the world of another domesticate. Despite this, a very large number of wild horse lineages were introduced in the domestic population (Vilà et al. 2001; Jansen et al. 2002; Achilli et al. 2012). This could indicate a widespread deliberate incorporation of this new species into human groups, which may be associated with improved transport and warfare capabilities (Vilà et al. 2006). The introduction of horses would have had a dramatic impact on many human cultures. This is well illustrated by the historically documented changes in the Native American groups which rapidly adopted horses after their arrival to the Americas with Europeans in the sixteenth and seventeenth centuries. This gave groups with horses a competitive advantage over horseless neighbors. A similar process likely occurred across Eurasia starting around 5500 years ago.

Unlike other domesticates in which there was a focus or a few foci of domestication from which domesticated animals expanded, the appearance of horses may represent the expansion of an idea. Under this scenario, horses were domesticated in one or a few places in the Eurasian steppe and from there spread to neighboring cultures, where large numbers of local wild horses, possibly primarily mares, were captured and used to reinforce domestic stocks. This view is supported by the large amount of female-inherited (mitochondrial) genetic variation (Vilà et al. 2001; Jansen et al. 2002) and the small male-inherited (Y chromosome) genetic variation (Lindgren et al. 2004) as compared to wild horse populations in the Pleistocene (Vilà et al. 2001; Lippold et al. 2011) and by the linkage disequilibrium in the whole genome (Wade et al. 2009). However ancient domestic horses had much more Y chromosome variation than modern animals (Librado et al. 2017), suggesting a major bottleneck for males associated with more modern breeding practices. By fitting a spatially explicit model to genotype data from horses sampled across northern Eurasia, Warmuth et al. (2012) deduced that the domestication took place in the western part of the Eurasian steppe and that domestic herds were repeatedly restocked with local horses as they spread out of this area.

Despite the lack of obvious skeletal changes as a result of domestication, ancient DNA analyses have illustrated the early selection for alternative coat colors through the analysis of mutations for known coat colors (Ludwig et al. 2009), behavior, and physiology (Schubert et al. 2014). Wild horses were most likely dun, as is depicted in some cave paintings. Black may have become more common in wild populations in areas where the forest was expanding in the Holocene. Other colors are associated only with domestic horses and were identified from remains dating from 3500 years ago (Ludwig et al. 2009; Librado et al. 2017).

Horses today are divided into numerous breeds, many of which are maintained reproductively isolated from all others. Some of these breeds have very well documented recent origins, such as the Thoroughbred. Others have longer more obscure histories, such as the Arabian. Still others are the result of geographic isolation, such as the Icelandic. Although the breeds are easily distinguishable by nuclear markers, they do not have unique male- or female-inherited markers. This indicates that local breeds do not represent local domestications but originate from more recent isolation from a broadly mixed stock. In fact, the study of Viking-age horse remains showed that a great admixture of maternal lineages existed over a reduced geographic area more than a thousand years ago (Vilà et al. 2001, 2006). However, some maternal lineages show a somewhat restricted geographic distribution (Jansen et al. 2002; Achilli et al. 2012).

Households and Domesticity: Historical Archaeology

Annie E. Gray
SACE, University of Liverpool, Liverpool, UK

Introduction

The archaeology of households and the related area of domesticity are fields most often explored in relation to the nineteenth century and are dominated by work on sites in North America and Australia. Household archaeology is one of the areas where the close synergies between the archaeological record and text may be best exploited. The wealth of data on household composition from a personnel and financial point of view which exists for the nineteenth century is indicative of official preoccupation with categorizing and analyzing socioeconomic units in the period, out of which the very notion of the household as a definable concept may be said to have arisen. Such documents mean that excavated sites can be tied to individuals. In some cases, based on date range or occupation data, specific artifacts can even be linked to individuals, making the field one in which analysis can take place on both a macro and a micro level.

Definition

Household archaeology is a relatively newly defined area, emerging as a properly theorized

field in its own right only in the 1980s (Barile and Brandon 2004: 5–6). Its roots lie in the very movements which form part of the modern theoretical background, in particular North American concerns to preserve and present the domestic sites of its founding fathers from the 1850s. The emphasis on domestic sites was in itself part of a "cult of domesticity" which is now recognized as part of the contested ground which household archaeology seeks to address. By the 1960s, prevailing processual trends within archaeology had redefined the household as an economic unit, a complete entity in its own right, and one which could be used as the basis of pattern analysis. Current scholarship emphasizes the tensions within that unit, and seeks to explore the household on a micro level, unpicking tensions based on class, race, gender, and age, to name but a few.

The definition of a household, and therefore of household archaeology, is itself an issue. It is often defined by what it is not, rather than what it is: thus, not merely an economic unit; not bounded by narrow spatial boundaries; not defined by architectural conventions. It is generally accepted that a household comprises one or more individuals with an emotional, economic, or spatial tie to one another. At its most basic, a household may comprise a nuclear family of wife, husband, and children, living in one spatially distinct dwelling and using any associated outdoor space. However, a household always encompasses more than a family, not least due to the difficulty of definitively attributing deposits to individuals. The household must, at the very least, include lodgers and servants, whether live-in or living outside. Guests, both occasional and longer term, may also be included. On a wider basis, any individuals having ties to the base unit may be considered as being part of the household. That unit may not be familial: work on temporary camps, boarding houses, and institutions such as workhouses have all considered the issues involved. The result of this complexity has been that those explicitly considering the household within their analysis have had to clearly state their own definition of that term and use it accordingly.

The aim of household archaeology is to explore tensions within each household, and not to study units as if they are a homogenous whole. Recognition and exploration of the various interests, which make up an individual household, and interpretation of artifacts and spaces in the light of intra-household tension as well as inter-household relations form the basis of household-based archaeology. Hence, it is crucial to understanding class and, while little work has yet been done on extant sites, has potential to shed light on differing racial experiences within communities.

Furthermore, it is impossible to study households, especially in the core period of the nineteenth century, without an understanding of notions of domesticity (and, with them, a familiarity with wider issues around feminism and gender). At the beginning of the nineteenth century, the position of women in Britain and its colonies, along with North America, was the subject of fierce debate. Women were frequently cast in a negative role, ranging from frivolous spendthrifts, to more seriously undermining a nation's virility and with it, ability to wage successful war, a preoccupation of many countries, especially until the fall of Napoleon in 1815. These views had long been combated by an alternative view of women as civilizers, able to tame man's natural propensities toward violence and lead society toward more genteel and cultured ways. By the 1840s, pressure on women to cease work and concentrate their energies in the domestic sphere was building. Class identity played a huge role in defining the accepted role of women. In many ways, little changed for the upper and lower ends of society: aristocratic ladies had never worked for a salary, while working class women struggled financially if they did not. Among the middle class, across borders, a pattern of movement can be seen in which the workplace was separated from the home, and women thereby encouraged to give up their former roles as – often unpaid but nevertheless key – administrators and assistants in their husbands' businesses (Wall 1994). Emphasis was put on the role of women as mothers and wives, a discourse which both strengthened their authority within the home and undermined their relationship with the workplace.

In the USA, a quasi-religious "cult of domesticity" grew up, which influenced architecture and furniture design (Clark 1988), as well as the choice of material culture in those households in which one or more people subscribed to it. Yet ideologies of domesticity were by no means fixed, nor were they universally accepted. Most definitions of acceptable domesticity were promoted by the middle classes, and most contemporary sources reflect that view. Generally, three tenets were held to constitute the aspirational idea: the absence of working women; the concept of the home as a sanctuary; and the idea of childhood as sacrosanct, a time for education and play, rather than work and early adulthood (Lampard 2009). However, not only was the middle class not a homogenous group, but attitudes varied by country, region and, of course, within each household.

Key Issues

A primary concern of household archaeology is to explore notions of domesticity, often sited within a class context. Most published work on excavated sites, to date, has been predominantly working class, urban, and either North American or Australian. Several essays in the special issue of *Historical Archaeology* on the Five Points area of New York analyzed domestic sites, with the issues raised by work on households running strongly through them (Yamin 2001). One driver, especially in this case, but also in exploration of The Rocks area of Sydney (Karskens 2003), has been to challenge popular views of particular urban areas as being slums. The definition of slum has been heavily influenced by middle class definitions of domesticity, and both the Five Points and The Rocks have been popularly seen as devoid of "homes," where home meant sanctuary and safety. Studies of these areas contradict such definitions, suggesting that middle class markers of domesticity, such as flowerpots and knick-knacks were embraced. Moreover, working class units, whether familial, individual, or communal, formulated their own ideas of the domestic.

A major interpretive theme is the question of how far the working class accepted middle class domestic ideals, and to what extent they adhered to them even when, for example, women and children had to work, either through financial exigency or personal choice. Evidence of flowerpots, figurines, vases, and toys for children is usually associated with the desire to adorn the home, while fancy hinges, picture hooks, and wallpaper are interpreted to show more dedicated structural change, often the case where occupiers are in residence for longer periods of time.

The integration of interpretation of the physical structure of each dwelling with smaller finds is ongoing. The emphasis away from architectural definitions of household and the drive to consider individual agency and action has led to a lessening of the exploration of space. More recent scholarship has considered space and gender through interpreting small finds (Yentsch 1991), but it is unclear how best to bring together spatial elements with an artifact-led approach.

Current Debates

Related to the definitional difficulties is discussion over what constitutes a household. While the general approach of multiple definitions has been accepted, it still poses problems for an integrated approach. The inclusion of nontraditional households such as cooperatives, boarding houses, and camps within the corpus of work in the field can pose difficulties (Beaudry 2004).

Emerging from economic definitions of the household in the 1960s–1970s, along with Marxist and post-Marxist emphasis on production, the role of the household as producer and reproducer is a key area for debate. Current scholarship looks both at the obvious aspects of production – homeworking such as taking in laundry or sewing – and the more nuanced role of the household in reproducing morals and belief systems grounded in a particular set of circumstances.

Archaeological data used in the exploration of households and domesticity tends to be small

finds. Beyond the dominant artifact groups of ceramics and glass, household-related items such as sewing ephemera, especially buttons; toys; fittings from furniture; parts of technical and musical instruments; and writing implements are all well represented in samples. Debate over the interpretation of these is evident across the field. For example, sewing equipment may be indicative of appropriate, domestically focused feminine activity, or it may show one or more women in the household were working from home. Pins may form part of a sewing kit, but they may also simply have fallen off garments in an age where pins were much used as fasteners. If a household contains no women, sewing-related ephemera may still be present, at which point its usefulness as a gendered item may also be questioned.

Examples

Key work on households and domesticity can be found in an edited volume by Barile and Brandon (2004). The essays within it cover a variety of approaches and differing definitions of household and show the breadth of approaches currently being taken in the field. The most frequently used definition, of a group of people living for a stated period at a specific, bounded, location, can be found in work on urban domestic sites. Lampard (2009) compares three working class sites in Port Adelaide, Australia, to demonstrate the interaction of financial circumstances and personal choice in the acceptance and exhibition of middle class domesticity. Significant work has also be done on brothels, considering domesticity as a middle class construct which was deliberately aped in public areas of brothels, but interpreted in a working class context behind the scenes (Seifert 1991, 1994).

Outside the strict confines of archaeology, work on recipe books and kitchens has demonstrated the potential of material culture to elucidate the changing notions of "home" and the way in which domestic space was conceptualized and used. Use of inventory and probate data, rather than results from excavations, has demonstrated the multiplicity of uses to which a room might be put, negating easy assumptions of gender and assignation of spaces to individuals or interest groups within the household (Pennell 1998). More recent archaeological work has started to incorporate a wider time period, as well as using more data from documentary sources and collections showing, for example, the negotiation of household responsibility through objects, such as tea things, heavily imbued with domestic significance (Spencer-Wood 2013).

Future Directions

Most work on households has concentrated on class and gender. However, work on cultural differences between immigrant groups in colonial contexts (e.g., Lampard 2009) has shown alternative readings are possible. More significantly, racial aspects are starting to be explored (Beaudry 2004; Praetzellis and Praetzellis 2004; Rotman 2006). Although the houses of both free and unfree African Americans have been excavated and interpreted in North America, consideration of them in the light of the issues around households and domesticity has often been lacking. Very little work has considered the post-Bellum differences in notions of domesticity and the relative influences of class and race in the formation of household identity. Moving beyond plantation sites and into exploration of houses where the servant divide was racially distinct but which were never associated with slavery would be a potentially rich area for exploration, as would the households of the rich in general.

Indeed, there has been a marked avoidance of the households of the rich, with the exception of certain well-known historical figures. In the UK, where little has been published to rival the interpretive output from America and Australia on domestic sites, country houses have been

increasingly recognized as sites through which class and gender tension may be usefully explored. Inevitably, many of them are still standing, but useful work has been done where structural work has necessitated the removal of floorboards (Newman 2004). It has not, as yet, been subject to systematic analysis within the theoretical tenets of household archaeology. It would be useful to see further archaeological exploration of the acceptance of or resistance to notions of domesticity among the upper classes.

The field of household archaeology is not restricted to the nineteenth century, but much work has to date been concentrated there. This is in part due to availability of sites to excavate – there are many more nineteenth century examples than earlier – and partly due to the explicit discourse on domesticity which occurs in the mid-late nineteenth century. This discourse can be directly related to archaeological data, affording the archaeologist a clear set of hypotheses. The wealth of documentary data to aid in the task is also important. Contemporary debate over the domestic sphere and the role of women ranges far beyond this period, however, and it would be valuable to investigate the formation of households and conflicts within them in the light of the rhetoric of the seventeenth and eighteenth century, especially in Britain.

Households in the Ancient Near East, Archaeology of

Catherine P. Foster
Ancient Middle East Education and Research Institute, Oakland, CA, USA

Introduction

The archaeological study of houses and households in the ancient Near East has traditionally focused on aspects of architecture and domestic artifact assemblages to elucidate ethnic groupings and kinship structures. More recent investigations have broadened their scope to examine such diverse topics as craft specialization, gender roles, and site formation processes that are manifest in, and interpreted from, the archaeological remains of houses. Households in the ancient Near East served as the basic unit of society and as an important focal point for the enculturation of its members. It is a place where social norms were learned, created, and disseminated and can thus be argued it formed the physical and psychological foundation for civilizations in this region.

Definition

The study of the practices, behaviors, and sociocultural structure of domestic groups or collectives related through kinship or shared activities. Households offer a window onto the everyday actions of people in the past. As a microcosm of society at large, households can also serve as linking agents between theories of social change and material culture.

Key Issues/Current Debates/Future Directions/Examples

Archaeologists do not excavate households directly. Instead, they must derive their impressions of households and the activities they performed in the past through the physical remains of those activities, including the construction, habitation, and destruction or abandonment of domestic dwellings or houses. A house is the physical structure in which households live, work, and play. Though households have many interests that are not always, or even usually, confined to the physical, architectural house, archaeologists have tended to rely on this focal point to offer clues about habitual household behaviors—cooking, eating, sleeping, creating, reproducing—and what these can tell about both "everyday life" (micro-narratives) and the effects of larger processes of social change (macro-narratives) on domestic groups.

Until recently, the archaeological study of houses and households remained underdeveloped in ancient Near Eastern scholarship. Excavations of large public buildings like temples and gateways, and private royal residences and palaces dominated the field. Thus, theoretical emphasis was traditionally placed on elucidating political history, large-scale economic and social systems, and royal and religious elite participants in these systems. True household investigations have become more of a focus in the last 25 years as the importance of domestic economy and social organization is increasingly recognized as crucial factors in the overall development of complex political, economic, and religious institutions that define the ancient Near East.

Today, archaeologists strive for a holistic approach to households by combining architecture with domestic assemblages, ecofacts, and site formation processes. These data are derived from field methods that take advantage of the full suite of scientific archaeological specialties including zooarchaeology, paleoethnobotany, lithic studies, and, increasingly, microarchaeological techniques. These involve the study of the microscopic archaeological record comprised of "residues" from human behaviors and natural formation processes that remain generally unseen to the naked eye in artifacts, features, or deposits. Examples of these techniques include geochemical analysis to detect ancient use of fire in domestic contexts (Alperson-Afil et al. 2007), microstratigraphy to chart the preparation and creation of living floors (Matthews 2001), and

microartifactual analysis to identify room use patterns or even deeply buried archaeological sites (Rainville 2005). Ethnoarchaeological studies in the modern Middle East have also provided interpretive frameworks by which to understand architecture, the use of space, and artifact assemblages (Watson 1979; Kramer 1982).

The most prolific application of household archaeology in the ancient Near East is reserved for prehistoric periods. Households of the Paleolithic/Natufian (c. 12,000–9,000 BCE.) and Neolithic periods (9,000–6,000 BCE.) in particular have garnered the greatest concentration by scholars who are interested in the social dynamics of hunter-gatherer groups, the adoption of sedentary agricultural practices, and how this latter change affected the social composition and framework of communities. It is here that remains of (now permanent) domestic structures—in the form of ovoid, cell, tripartite, or "megaron/pier" rectangular houses—play a key role. Architectural change has come to be seen as reflecting social change in, for example, newly developed strategic floor plans that impeded movement and developed social barriers at places like Basta (Kuijt 2000). Others argue that new building configurations were accompanied by psychological shifts, as households reconceptualized the physical house as symbolic "home" at Qermez Dere (Watkins 1990), Baida, Jericho, Jarmo, Hacilar, and other sites. Architectural changes over time for a single house can also be manifestations of changes in the coresidential group. These dynamic shifts can be brought about by multiple factors such as adjustments to room function, subdivision of private property through inheritance, ideological developments, physical deterioration of the building, or, as at 'Ain Ghazal, shifts in household composition over the course of a few generations (Byrd 2000; Banning 2003).

Perhaps the most progressive studies of prehistoric households in the ancient Near East are centered at the Neolithic site of Çatalhöyük in Anatolia. Exceptional preservation has allowed the multidisciplinary team to examine the entire use life of domestic structures, from construction and habitation to destruction and/or abandonment. The Berkeley Archaeologists at Çatalhöyük (BACH) team meticulously excavated a single house to reveal five major building phases characterized by a series of floors, fire installations, platforms, post-retrieval pits, bins, and niches (Fig. 1; Tringham and Stevanović 2012). Good preservation ensured the recovery of residues from woven baskets, a domed clay oven, and even the entire collapsed roof. These remains served as a template for a modern replica of the Neolithic house where the application of experimental archaeology provided information about the physical experience of living in these prehistoric dwellings, from working in smoky conditions to negotiating the narrow ladder to access the rooftop entrance. Others have focused on the social and psychological roles of houses (*domus*) specifically as the vehicle by which both wild animals *and* humans were domesticated. Though the factors behind human sedentarization remain contentious, Hodder (1992) has argued that Neolithic peoples accepted the constraints of sedentary lifestyles and agricultural production because the institutions of house and home were believed to ensure continuity as well as protection against the various perceived dangers of the outside natural world.

The development and characteristics of households within urban settings have also received increased attention in Near Eastern archaeology. At the dawn of urbanism in the ancient Near East, households appear to have retained productive control over such products like ceramics and chipped stone tools in the face of growing specialization and centrally administered facilities, a dynamic best exemplified at Tell Abu Salabikh (Pollock et al. 1996). This trend continues into the late third millennium BCE. when, at a time of increasing political centralization in the region, it appears that some households chose to acquire select specialist products with a high degree of social visibility, like serving vessels and textiles, instead of producing them domestically. Nonelite households were thus actively engaged in the creation of a social system demarking elite status through the demand for prestige-laden products (Wattenmaker 1998). These studies illustrate how households played important roles in complex systems of increased craft specialization and

Households in the Ancient Near East, Archaeology of, Fig. 1 An example of a Neolithic dwelling from Catalhöyük (Building 3, phase B3.4A) with raised platforms, an oven in the south, and basins and bins along the west wall. (Çatalhöyük Research Project; Reused with permission by Cotsen Institute of Archaeology Press)

centralization, with the simultaneous retention of cottage industries.

In the southern Levant, urbanization—as viewed through a household lens—was a process whereby communities transformed their built environments to create new patterns of economic and political relationships and realign social identities while maintaining kinship bonds and alliances (Chesson 2003). This process was not a determined continuum, but instead a disjointed development that favored an outward ideology of uniformity in domestic architecture (i.e., "broadhouse" and "front-room" house) and city planning, best seen at sites like Tel Bet Yerah and Arad (Greenberg 2003). Later, household groupings and alliances were to become powerful forces

within ancient cities. The work by Stone (1987) at Nippur—which combined architecture, artifact assemblages, textual sources, and analogous patterns of urban residence in Islamic cities of the modern Middle East—shows the structure and life histories of urban households during the second millennium BCE. which determined the long-term social development of particular individual neighborhoods or quarters on a local scale, as well as the city as a whole.

For the Iron Age (c. 1200–612 BCE.), most scholarly attention has been paid to documenting and characterizing domestic buildings in the southern Levant. It is here that a standardized architectural form became dominant between the eleventh and sixth centuries BCE. after a period of development stretching back as far as the thirteenth century BCE. The so-called four-room house and its three-room subtype—composed of living and storage spaces encircling a central open courtyard—have been attested at multiple urban and rural sites including Tell el-Far'ah (N), Tell en-Nasbeh, Shechem, and Beersheva (King and Stager 2001; Schloen 2001). These buildings housed either nuclear or extended families or households, and they can be found in both urban and rural settings (Fig. 2). Until recently, these and other house forms (notably Aegean building traditions) and associated artifact assemblages were examined chiefly to characterize ethnicity ("Israelites," "Philistines," "Canaanites"), group identity, and/or family structure. The power of the text in biblical archaeology has led scholars to ignore aspects of gender, household production, and status in favor of house form and dietary indicators of ethnicity (Yasur-Landau et al. 2011). This is changing as more scholars begin to explore domestic economies, the physical use of space within domestic compounds, and aspects of gender relations that crosscut all household segments.

Still, several fundamental issues remain for the archaeological study of households in the ancient Near East. Beyond studies of prehistoric sites that, on the whole, grapple with the limits of preservation and sample size, other studies narrowly focus on a single house or household group at a site and do not consider its position within the larger contexts of the local community and the region. Households do not exist in a vacuum; they are affected by sociopolitical or economic conditions that exist beyond their front doors. Diachronic investigations are also essential for seeing the entire picture of domestic life; however, archaeologists often do not account for internal fluctuations or variation between household groups over time. Nor do they always consider aspects of natural and cultural formation processes of the archaeological record that not only affect household remains but all ancient contexts. Post-depositional processes are sometimes overlooked in household investigations in the Near East, where there is a frequent assumption that objects are excavated in their place of use. The application of microarchaeological techniques is beginning to address this problem, but their use remains limited.

Deeper theoretical considerations of ancient Near Eastern households are heavily weighted toward prehistoric contexts, where textual documentation is not available. Scholars of these early periods have managed to tease out the subtle nuances of ancient human behaviors, social structures, and cultural underpinnings based on archaeological materials and ethnographic parallels. On the opposite end of the scale, there remain fundamental gaps in our knowledge about later period households, most notably from Neo-Assyrian (c. 883–612 BCE) contexts. In this case, Assyriologists have provided the most information about households of the ancient Near East, particularly royal ones, through letters and inscriptions, but examinations of archaeological data remain woefully neglected. Thankfully, research projects at sites like Ziyaret Tepe and Ayanis in Turkey are beginning to address this lacuna for both provincial Assyrian and Urartian households alike.

Finally, the archaeological study of households has tended to favor the nonelite portions of society as scholars seek to understand the daily lives and interactions of the majority of the population. However, the palace was both a place of business and home to the royal family and their attendants and staff and would in theory also be amenable to household archaeological investigation. While legacy collections from excavations during the late nineteenth and early twentieth centuries do

Households in the Ancient Near East, Archaeology of, Fig. 2 Tightly packed Iron Age house compounds with narrow street at Tell en-Nasbeh; scale: one grid square equals 10 m^2. (Reused with permission by Badè Museum, Pacific School of Religion)

not allow for particularly nuanced examinations of palaces beyond architecture and monumental artistic programs, contemporary excavation techniques and household archaeological theory allow scholars the opportunity to reexamine palace life as a lived experience with its own daily rhythms and many social actors.

Houses and households of the ancient Near East form a core dataset by which archaeologists can examine the everyday life of families and communities. They simultaneously offer a glimpse into the mundane and provide a lens by which to magnify the actions of people whose relationships weave together the fabric of society. Beyond providing basic shelter, houses are embodied spaces that both exhibit and reinforce cultural rules, practices, and beliefs. In short, they are a microcosm of society at large. Their inclusion in any truly holistic investigations of cultural, political, or economic developments within or between sociocultural groups of the ancient Near East is thus imperative (Parker and Foster 2012).

Hrdlička, Aleš

Maciej Henneberg
School of Medical Sciences, University of Adelaide, Adelaide, SA, Australia

Basic Biographical Information

Aleš Hrdlička, a pioneer of American biological anthropology, was born in 1869 in Humpolec in the Vysočina Region located between Prague and Brno in the present-day Czech Republic. Hrdlička was a founder of the Division of Physical Anthropology at the US National Museum of the Smithsonian Institution (now the National Museum of Natural History, under the same institution), and of the *American Journal of Physical Anthropology* – one of the 10 most influential biology and medicine journals of the century.

At the time of his youth, the area where he was born belonged to the Austro-Hungarian Empire. The Empire had an excellent system of education encouraging intellectual development of all children, irrespective of their socioeconomic status. From an early age, Aleš, the oldest of the seven children of an artisan cabinet maker, showed great aptitude for learning and interest in natural history. When he emigrated with his father to the United States of America at the age 13 years, he had to work in a cigar factory to help his father to earn a living for the family who followed them later to America. Hrdlička completed his education at evening courses.

At the age of 18, Aleš fell seriously ill with typhoid fever and tuberculosis. This period of illness led to his interest in studying medicine. He entered the Eclectic Medical College in New York, graduating as the first in his class in 1892 and continued his studies for the next two years in the New York Homeopathic Medical College. After graduation in 1894, he became a physician at the State Homeopathic Hospital for the Insane in Middletown, New York. Following his early education that compelled him to conduct objective observations, he became interested in reliable measuring of the human body and the brains and started his lifelong research in anthropometry and physical anthropology. Moving as a researcher to the newly established Pathological Institute of the New York State Hospital, he had an opportunity to travel to Paris to study biological anthropology in the Ecole d'Anthropologie with Leon Manouvrier, the successor to Paul Broca, the founder of the Ecole.

Upon return to New York, Hrdlička applied his skills in anthropometry to accumulate large samples of measurements of patients in various hospitals by involving about 20 collaborators. As a physical anthropologist, Hrdlička joined the Hyde Expeditions which were run by the American Museum of Natural History and nominally overseen by Frederick Ward Putnam of the Peabody Museum at Harvard. At the turn of the twentieth century, these expeditions were exploring all aspects of archaeology and anthropology of the American Southwest. During those regular trips to the Southwestern United States and Mexico, he accumulated observations on Native Americans that sparked his interest in their origin. When in 1903 the National Museum in Washington, DC created the new Division of Physical Anthropology, Hrdlička was given charge of this Division as an Assistant Curator. Promoted to full Curator seven years later, he remained in the Division for the rest of his career, finally retiring in 1941.

Major Accomplishments

During his studies that took him all over the world, he accumulated extensive osteological collections for the Museum, later renamed the Smithsonian Institution. These collections remain an important resource for anthropological studies, though many are now subject to repatriation. He was an indefatigable missionary for the discipline of physical anthropology establishing in 1928 the American Association of Physical Anthropologists which today is the largest, and to a certain extent international, association of biological anthropologists in the world. Although a leading figure in American anthropology, Hrdlička did not neglect his country of origin. He subsidized the foundation of a Chair of Anthropology at the Charles University in Prague that is still an important center of biological anthropology today. He also funded exploration of prehistoric sites by Czech Academy of Sciences and Arts. There is the Hrdlička Museum of Man in Prague and International Anthropological Congresses of Aleš Hrdlička are regularly organized by Czech anthropologists.

Aleš Hrdlička was principally an observer and a describer rather than a theoretician. He precisely measured large numbers of human skeletal remains of various peoples all over the world. Working in the era when physical anthropology was heavily involved in the studies of human races and their dangerously misinformed outgrowth of racism, he largely avoided drawing any conclusions about the superiority of one race over others. He maintained that all human races had a common origin in the Old World. His meticulous studies of Native Americans lead him to postulate that Americas were settled fairly recently (in the last 15,000 years) by people moving in from Asia through Bering straits.

There are more than 350 items in Aleš Hrdlička's bibliography. From the year of his graduation in 1894, he published an average of eight papers a year. Among his most important books are the following: *Catalogues of Human Crania in the U.S. National Museum* (1924, 1927, 1928, 1940, 1944); *Brain Weight in Vertebrates* (1905); *Physiological and Medical Observations among the Indians of Southwestern United States and Northern Mexico* (1908); *Early Man in South America* (1912); *Anthropometry* (1920) republished as expanded *Practical Anthropometry* in 1939; *The Skeletal Remains of Early Man* (1930); *Melanesians and Australians and the Peopling of America* (1935); *Diseases and Artifacts on Skulls and Bones from Kodiak Island* (1941), and *Alaska Diary* (1943).

Although married twice (1896 and 1920), Hrdlička had no children. He was considered by many as a man of authoritarian character delivering arbitrary judgments. In the words of M.F. Ashley Montagu (1944), an American anthropologist and humanist who popularized major themes of anthropology "Hrdlička was a kindly soul, and appeared much more formidable than he really was." This agrees well with the translation of his name into English – a turtledove. Aleš Hrdlička died on 5 September 1943.

Huashan Mountain Petroglyphs

Su Sheng
Rock Art Association of China, Beijing, China

Introduction

The Huashan Mountain petroglyphs are located in Ningming County, Guangxi Province, in southern China. In addition to the rock art of Huashan Mountain itself, a total of 79 petroglyph sites, painted in a similar style and on steep cliffs, have been found along the Zuojiang River in this region. These petroglyphs usually are found at elevations higher than 20 m above the ground or water surface (i.e., for cliffs fronting the river) and can extend up to 80–120 m above the surface (Figs. 1, 2, 3, and 4).

Definition

All the images are painted in varying hues of reddish-brown color. While human figures are most commonly represented at all these sites, representations of dogs, birds, and implements such as knives, swords, and bells are also found. While some humans seem to be dancing or performing other ritual acts, some are seated in boats, and a few appear to be engaging in sexual intercourse. Huashan Mountain itself is the largest

Huashan Mountain Petroglyphs, Fig. 1 Details of the most well-known site

Huashan Mountain Petroglyphs, Fig. 2 Main panel

Huashan Mountain Petroglyphs, Fig. 3 Details of one of the panels

Huashan Mountain Petroglyphs, Fig. 4 Detail of one motif

of the known sites in this region. About 1819 figures can be seen on a cliff 210 m wide and extending 50 m above the Zuojiang River.

Key Issues/Current Debates/Future Directions/Examples

Based on implements interpreted from the images, associated archaeological materials, and C-14 dating, it is estimated that the Huashan petroglyphs were drawn in four stages sometime between the early Warring States Period and the Han Dynasty (c. 475 BCE–CE 220). The initial stage dates to the early and middle period of the Warring States. The main fluorescence of the paintings was in the second stage, between the later Warring States Period and the early period of the Western Dynasty. While still flourishing, rock painting began to decline during the middle and later period of the Western Han Dynasty. The fourth and final stage of painting took place during the Eastern Han Dynasty.

According to the historic records, the rock paintings were executed by the ancestors of the modern "Zhuang" people, the largest native ethnic group in the Guangxi region. According to Zhuang myths, legends, and traditional religious beliefs, the ancestor deities have many functions. The Huashan petroglyphs express the worship of ancestors to invoke their aid in preventing natural disasters of flood and drought, to ensure a flourishing population and to bless and protect Zhuang warriors.

The Huashan rock paintings were drawn mainly by outlining of figures in rough lines and in a style of primitive simplicity without details. The artists were rather good at composition, clearly portraying the main characteristics of human figures, animals, and implements. These petroglyphs use strong color and primitive lines, emanating an atmosphere of great zeal and mystery. The Huashan petroglyphs exhibit a style that is distinct from that of other regions.

All the Huashan petroglyphs show evidence of damage to varying degrees from a combination of

natural and man-made causes. Many images have become incomplete and blurred, and some of them cannot be recognized. Sometimes there are only some mottled spots left. So far, there has not been any effective scientific means to prevent further damage from the natural elements, even if protected from human-caused damage. It is necessary to organize concerned experts to carry out experiments and scientific research to identify ways to better conserve these petroglyphs. At the same time, these and other rock arts need to be protected from human-caused damage. This work would benefit from collaboration between rock-art specialists and concerned scientists in China and abroad.

The rock art of the Huashan Mountain region is the precious cultural heritage left by the ancestors of the Zhuang people. The grand scale of the rock painting and its stylistic characteristics are seldom seen in other places. It has great academic value for cultural and religious history, archaeology, and the history of fine arts. It is natural that interpretations of this rock art vary in different academic circles at present, but we are confident that the differences will be reduced with further scientific research.

Human Evolution: Multiregional Origins

Milford H. Wolpoff
Department of Anthropology, University of Michigan, Ann Arbor, MI, USA

Introduction

Understanding human phylogeny has always been contentious. For more than a century after Darwin, human phylogeny usually reflected current racial taxonomy. Through the end of the nineteenth century and into the twentieth, most paleoanthropologists and paleontologists were evolutionary polygenists who essentially described human races (=subspecies) as having independently evolved from different primate species, some ancient and others more recently (Wolpoff and Caspari 1997). In the twentieth century, evolutionary polygenism had come to focus on the independent evolution of human races (=subspecies) from a single prehuman hominid ancestor. The key element all variations of evolutionary polygenism had in common was the independent evolution of human races for so long that the races acquired their humanity separately (Wolpoff and Caspari 2000).

Even in its heyday evolutionary polygenism was not accepted by all paleoanthropologists, and after the end of the Second World War, as biological races lost any vestige of scientific validity (Caspari 2010), prominent evolutionary schemes could no longer be based on them (at least, not without repercussions). This polarized the developing interpretations of human variation and consequently theories of human evolution. For some, variation in the human fossil record was elevated to become species variation, a viewpoint prominent among scientists who accepted the punctuated-equilibrium theory. For others, the taxonomy of human variation was reduced to a lower level, and the null hypothesis became one of a single species lineage. A reduced number of species lineages were recognized in the human fossil record, and only one in genus *Homo*

(at the extreme, see Wildman et al. 2003). The predominant single lineage model for *Homo* (Wolpoff et al. 1994) is explained by the hypothesis of Multiregional Evolution (Wolpoff et al. 1984, 2000).

Definition

Multiregional Evolution describes the pattern of Pleistocene human evolution (Thorne and Wolpoff 1992). It describes a long-term evolution of central (African) and peripheral populations in the widespread polytypic human species that, in recent times with expanding populations, changed to no longer be polytypic (Wolpoff et al. 1984). This evolutionary pattern was structured by the initial and ongoing geographic dispersals of human populations (Hawks 2011) and their continued interconnections through gene flow and population movements allowing adaptive genes and behaviors, under selection, to spread throughout the human range. The key aspects of the multiregional pattern combine global evolutionary changes under selection, as adaptive genes disperse (Hawks and Wolpoff 2001), with continuity over time for regionally prominent features in various parts of the world, especially the peripheries – "regional continuity" (Wolpoff et al. 1984; Wolpoff 1989). This is an ethnogenetic pattern (Moore 1994) in which populations exist within a network, usually with both multiple ancestors and multiple descendents, and the trends in human evolution are universal as genes under selection evolution disperse throughout the network of interconnected populations.

Multiregional Evolution, in Templeton's words (2007: 1511), "is not just a single alternative of recent human evolution, but rather is a class of models. . . . Population genetic theory and observations indicate that there is a broad range of conditions that will result in this pattern." Examples of this class of models, besides those directly described as Multiregional Evolution, include the "assimilation model" (Smith et al. 2005), "hybridization with continuity" (Wu 1998), and "regional continuity" (sensu stricto) from Trinkaus (2007). Constructs such as the "Afro-European sapiens hypothesis" (Bräuer 1984) might also be considered this way, but the fit is not as clear.

The human species was quite small for most of the Pleistocene, totaling as little as one million or less (Eller et al. 2004). Multiregional Evolution is a consequence of its population structure and the fact that its populations were intermittently connected in a network of gene flow and population movements. It is likely that half or more of the human species lived in Africa, until the still ongoing population expansions beginning at the end of the Pleistocene, and this superimposes the multiregional pattern across the human range because the direction of gene flow across this interconnected network is very often from the center of the human range, where there were more people, to the various edges. In our first description of Multiregional Evolution (Wolpoff et al. 1984), we described a "center and edge" pattern in which most gene flow went from the African center with its large population to the more sparsely occupied peripheries. This has been a persistent pattern in the Pleistocene; the movement of genes from the center often brought new adaptive genes to the peripheries, but regional features were also maintained there, and at no time did the African features fully replace the regional ones. Two elements combine to strengthen this pattern: (1) the fact that with more people there were more adaptive mutations in Africa and (2) the several distinct dispersals out of Africa (Templeton 2007) that superimpose over lesser magnitudes of sporadic, continued gene flow.

The conditions are different at the peripheries where some differences between populations appeared (Fig. 1) – in human evolution, these are regions such as China, Europe, and Indonesia – where gene flow across the network of interconnected populations "can be a strong force that inhibits peripheral populations from evolving to their local ecological optima . . . as a result peripheral populations experience persistent directional selection" (Garcia-Ramos and Kirkpatrick 1997), the "center and edge" effect. This pattern of variation, relating the center and the various edges of humanity, is reflected in the

Human Evolution: Multiregional Origins, Fig. 1 The multiregional pattern at the human peripheries is shown in the comparison of archaic humans (*below*) from East Asia (Dali, *left*), Australasia (Sangiran 17, *center*), and Western Europe (La Chapelle Neandertal, *right*) with their recent counterparts. Regional features include, among other things, prognathism (little, alveolar, total facial), cheek orientation (forward or side facing), and nasal projection. In all cases, the recent crania (*above*) are higher, shorter, and rounder with smaller faces and less prominent buttresses, reflecting global changes in the human species

regional continuity of different anatomies in different places that extended beyond the time of initial colonizations (Wolpoff et al. 1984) and through continued Pleistocene dispersals (Templeton 2007). But finally, as the significant population expansions and movements of the late Pleistocene and more recent times began (Hawks et al. 2007), the ancient pattern of distinct regional differences (subspecies) was obscured. One consequence is that today variation within populations is greater than variation between populations, and subspecies (biological races) do not exist. Only some manifestations of the Pleistocene population structure can be found in recent populations (Fig. 1).

The key insight of Multiregional Evolution is that it describes evolutionary changes *within* an evolving species (lineage), not evolution as one species replaces another. Evolutionary history and local adaptive variations are related by selection throughout the Pleistocene, to account for how genetically interconnected populations in the widespread human species developed and maintained significant geographic differences, while the dispersal of adaptive genes under selection accounts for the global, adaptive evolutionary changes. Toward the end of the Pleistocene, this global pattern was increasingly obscured, as dramatic population size expansions from approximately one million humans, with concurrent dispersals and some population extinctions in the Neolithic, came to characterize the still expanding human species.

Key Issues/Current Debates/Future Directions/Examples

There have been ongoing debates about Multiregional Evolution since its first publication 30 years ago. If correct, the Eve replacement theory would be the disproof of Multiregional Evolution, and the question of whether this disproof is valid is the most important recent debate.

The Eve replacement theory posits that human evolution occurred by speciation and modern humans originated from a single, unique ancestral population living between 100 and 200,000 years ago in Africa that gave rise to and closely relate all of humanity. It would mean that modern humans are a new species that replaced all archaic populations without mixture. Like any theory, the Eve replacement theory can be tested, and new discoveries have made this alternative theory invalid to its supporters:

> The recent finding that significant interbreeding occurred between Neanderthals and modern populations refutes the long-standing model that proposes all living humans trace their ancestry exclusively back to a small African population that expanded and completely replaced archaic human species, without any interbreeding. (d'Errico and Stringer 2011: 1060)

Even before these findings, anatomical evidence from the human fossil record indicated that at the furthest peripheries of Europe and Australia, there is statistically significant evidence for dual ancestry of the earliest modern populations, one in African descendants and the other in local archaic populations (Wolpoff et al. 2001).

Subsequent studies of ancient genes and the human genome reveal more key details about past population movements and structure and directly address the multiregional issue. Neandertal genes dispersed under selection, in many cases long after the genes first appeared, into non-African populations where they led to significant adaptive changes (Hawks et al. 2008; Green et al. 2010). Neandertal genes persist in both Europe and Asia, but for the most part, the persisting genes in these two regions are different. This suggests two things: (1) a common region where the mixture took place – almost certainly the Levant, where anatomical evidence (Fig. 2) first suggested mixture of Europeans with Africans for more than a half-century, and (2) the likelihood that very small populations were involved in the incidences of mixture, wherein random loss of genetic variation from drift could play a significant role.

Nuclear DNA of a non-Neandertal specimen from Denisova Cave in Siberia (Reich et al. 2010) provided further evidence of intermixture, between a different lineage of archaic hominids and other ancestors of modern humans. The Denisovan and Neandertal lineages share a common ancestor that is more recent than the common ancestor with Africans. In further work, Skoglund and Jakobsson (2011: 18301) concluded:

> In addition to the previously reported gene flow between Neandertals and non-Africans as well as gene flow between an archaic human population from Siberia ("Denisovans") and Oceanians, we

Human Evolution: Multiregional Origins, Fig. 2 Middle Paleolithic Levant specimens from Skhul (*left*) and Tabun (*right*) contrast anatomies that may reflect (respectively) primarily African and European descent. Some authors have regarded these two as "early modern" and "Neandertal" crania, but anatomy and archaeology reveal that these and other Levant specimens from the Middle Paleolithic reflect mixed descent

> found a significant affinity between East Asians, particularly Southeast Asians, and the Denisova genome. ...These results suggest admixture between Denisovans or a Denisova-related population and the ancestors of East Asians.

The extent of mixture between these two archaic lineages and Africans was significant and persistent; ancient populations, meaning Neandertals and the Denisovan Asians, account for some 8% of the ancestry of living non-Africans in one estimate from Reich et al. (2010). This is a substantial percentage, given the likelihood that these were small, peripheral populations at the northern margin of the Eurasian range. This growing body of new information fleshes out the details of Multiregional Evolution in ways that the fossil record could not address. The perseverance of Neandertal and Denisovan genes in significant numbers marked the end of the Eve replacement theory. But support for Eve replacement will not end so easily because science is a *human* activity.

Human Evolution: Theory and Progress

Djuke Veldhuis[1], Peter C. Kjærgaard[1] and Mark Maslin[2]
[1]Department of Culture and Society, Aarhus University, Aarhus, Denmark
[2]Department of Geography, University College London, London, UK

Introduction

In one of the most remarkable understatements in the history of science, Charles Darwin wrote about his theory of evolution by natural selection that "light will be thrown on the origin of man and his history" (Darwin 1859: 488). That was practically all Darwin was prepared to share about the consequences for humankind of his theory in the *Origin of Species*, the seminal work on modern evolutionary ideas. But everybody around him immediately understood the implications, and as archaeological evidence and human fossil remains accumulated during the nineteenth and twentieth centuries in combination with genetic data, theories of human origins eventually became the science of human evolution.

Often overlooked, but central to Darwin's original method and the force of his argument, is the power of converging evidence from a number of different disciplines and bodies of knowledge. For the general theory of evolution, these originally included geology, paleontology, zoology, botany, physiology, anatomy, and, famously, selective breeding. Similarly, human evolutionary studies today are characterized by their multidisciplinarity. Whereas archaeology and paleoanthropology have been central to defining early human history, pushing the chronological boundaries of the first of everything further back in time, they no longer stand in unique positions to the understanding of the evolutionary history of humans.

Definition

Every extinct and extant species on earth have resulted from the same evolutionary processes determining the way they are through shaping their morphology, physiology, and behavior. The traits specific for the human species are the result of the same evolutionary processes responsible for any other living creature. From a general evolutionary perspective, humans are consequently no different than any other species on the planet. Human evolution refers to the natural process involved in the evolutionary history of all members of the human clade (consisting of *Homo* and other members of the human tribe, *Hominini*, after the split from chimpanzees and bonobos). Members of the human clade are referred to as hominins. Previously, the date, nature, and identity of the last common ancestor between modern humans and their closest living relatives were determined on the basis of comparative anatomy of living species and fragmentary fossil remains. Today, molecular genetic data play an increasing role in establishing phylogenetic relatedness between hominoids, the superfamily including all living and extinct ape and human species. Theories of human evolution refers to the complex defining methods, practices, hypotheses, models, explanations, and interpretations of data, answering the question what makes us human from an evolutionary perspective.

Historical Background

Nineteenth-century discovery of early human archaeological and fossil remains led to a systematic investigation of human origins using a scientific explanatory framework. The gradual acceptance of deep time that eventually included humans gave rise to the scholarly division of human history into history and prehistory. Deep history was connected to a deep evolutionary ancestry with the introduction of the scientific theory of descent with modification. A number of key events and publications were instrumental in shaping early theories of human evolution, including among others the publication of Darwin's *Origin of Species* (1859) and *Descent of Man* (1871), Charles Lyell's *Geological Evidences to the Antiquity of Man*, Thomas Henry Huxley's *Evidence as to Man's Place in Nature* (1863), and John Lubbock's *Pre-Historic Times* (1865), the discovery of Neanderthals in Gibraltar, Belgium, Germany, and France, along with archeological artifacts such as stone tools and kitchen midden remains from early settlements, and cultural expressions such as cave paintings found in Spain and France.

From the second half of the nineteenth century, theories of human evolution were largely driven by discoveries. Archeological evidence, which includes any objects that have been made by hominins, played an important part in generating evidence and establishing theories about the behavior of early modern humans. Comparative anatomy, which reasons that organisms that are closely related to each other share many anatomical similarities, was another source of knowledge establishing evolutionary kinship. But fossil evidence was generally seen as most important to prove evolutionary theory right, leading to a race to find the Missing Link connecting humans and apes (Reader 2011; Kjærgaard 2011).

With a limited fossil record, many questions in human evolution remained speculative. It was thus more a theoretical preference and indeed the

order in which fossils were discovered at different locations that determined the favored geographic local of human origins. Darwin had tentatively suggested Africa, but he was a minority. Asia was generally seen as the most likely place for the cradle of humankind, which was supported by Eugène Dubois' recognition of the first *Homo erectus* (1891–1892) found, at the time known as the Java Man echoing the location of the excavations. With a number of fossils turning up in Germany, France, Belgium, and Britain, including the first recognized Neanderthal (1856), *Homo heidelbergensis* (1907) and the notorious Piltdown Man (1912), Europe entered the race to find the first human. The discovery of *Australopithecus africanus* in South Africa 1924 was initially met by skepticism and the location of the true origin of humans remained undecided.

With the increasing number of early human fossils, in particular from Africa (Fig. 1), the resolution of the human family tree got better. But still with so few fossils to build ancestral phylogenies, there continued to be great difference in opinion among leading paleoanthropologists. Some argued for few species, others for a larger variety of early hominins. These groups are commonly referred to as lumpers and splitters. The scarcity of fossil data also made room for radically diverging interpretations of the human family tree. For decades, there were two coexisting theories. The "out of Africa hypothesis" stressed descent of modern humans from a single common ancestor with a growing support for an African origin. The other so-called multiregional theory argued for a multi-linear theory of descent postulating regional origins of modern humans from different ancestral species. With the tides turning in favor of the "out of Africa hypothesis" in the 1980s, the multi-linear model gradually went out of fashion. Following the

Human Evolution: Theory and Progress, Fig. 1 Map of Africa showing the locations where key hominin species have been found

"fossil explosion," which has seen 11 new species and four new genera named since 1987, understanding of the range of variation in the hominin phenotype was much improved. Two further developments have since revolutionized the empirical base supporting human evolution and emphasized the importance of transdisciplinary enquiry: dating technologies and genetics.

Dating Challenge

There are four primary dating technologies: radiogenic isotopes, paleomagnetism, thermoluminescence, and electron spin resonance. Henry Becquerel, French physicist, discovered the natural radioactive decay of uranium at the turn of the twentieth century. Further work by Ernest Rutherford and Bertram Borden Boltwood indicated that the predictable decay of radioactive elements could be used to keep track of time. Not only did it confirm the earth to be billions years old, it provided the earliest empirical time scale for the fossil record. Common chemical elements used in dating include Argon, Carbon-14 (radiocarbon), and Uranium (Fig. 2). Which elements researchers use depends on how quickly they decay. For example, Carbon-14 dating is extensively used to date organic finds 60 Ka and younger as it has a relatively short half-life (the time it takes for one half of the atoms in Carbon-14 to disintegrate) of about 5,730 years. It has allowed us to accurately document the origins of agriculture, around 12 Ka ago, by dating the remains of animals and plants (Zeder 2011). Argon in contrast has a longer half-life and is extremely useful in dating finds older than 10 Ka. Argon-Argon dating has been used to date many of the fossil sites in East Africa and was also used to date hominin remains at Dmanisi in Georgia to 1.8 Myr old (Garcia et al. 2010).

Paleomagnetism uses the direction of magnetic particles in layers of sediment and compares these to the known shifts in the Earth's magnetic field over time. These shifts can be full reversals when the north magnetic pole suddenly becomes the south magnetic pole, or smaller changes in direction due to the magnetic pole wandering and variations in magnetic field strength. Most fossils are found in sedimentary rock which can be difficult to do date using radiogenic isotopes, and this is where paleomagnetism is a powerful alternative. Paleomagnetism was used to date *Sivapithecus*, a genus of extinct primates and probable ancestor to orangutans, to 12.5 Ma (Kappelman 1993). In this case, the paleomagnetic resolution exceeded the typical 5% error rate associated with radiocarbon (potassium-argon) dating.

Thermoluminescence and electron spin resonance (ESR) measure the amount of electrons that get trapped inside a rock or fossil over time. First developed in the 1950s, thermoluminescence

Human Evolution: Theory and Progress, Fig. 2 Effective ranges of major dating methods relevant to human evolution studies

works on the basis that crystals, such as quartz, trap electrical charges (electrons) at a known rate over time. If this crystal, for example, a flint blade, is heated, these electrons are liberated, emitting a measurable amount of light. This allows researchers to determine when an object was last heated. What is actually determined is the amount of elapsed time since the sample had previously been exposed to high temperatures. It is used to date volcanic materials and meteorite impact craters, but can also directly date past human activity such as when ceramics or flint materials were heated to improve strength and durability (Richter 2007). ESR also measures electrons trapped in the lattice, but unlike thermoluminescence, it does not destroy the sample being tested; this allows samples to be dated multiple times. ESR mostly tests calcium carbonate in limestone, coral, fossil teeth, molluscs, egg shells, quartz, and flint. Both methods are typically used to date samples from the last 300,000 years though theoretically they could be used on much older samples.

Genetic Revolution

Since the 1960s, the field of evolutionary genetics has arguably made the greatest impact upon human evolutionary studies. Advances in technology such as the development of the polymerase chain reaction (PCR) have been instrumental allowing, for example, the analysis of ancient DNA taken from Neanderthal fossils (Green et al. 2010). Allan Wilson, Emile Zuckerkandl, and Linus Pauling pioneered the use of molecular approaches, which examined evolution at the scale of DNA and proteins showing that relationships among living and extinct primates can be inferred from genetics as well as fossils. Genetics too can be used as a "clock," which compares the amount of genetic differences (mutations) between living organisms. Since mutations have predictable rates of change over time, they can be used to estimate how long ago a living species shared a common ancestor. The molecular clock cannot assign concrete dates and must be calibrated against independent evidence, such as the fossil record. Nevertheless, taking together the transdisciplinary evidence, we now have a robust understanding of the relationships between humans and apes. For example, we know that humans and chimpanzees split from their common ancestor approximately 4–8 Ma (Sarich and Wilson 1967; Gagneux and Varki 2001) and that the genetic difference between humans and chimpanzees is miniscule at about 1.2%.

Genetics has also confirmed that living humans have a limited genetic diversity indicating a series of population bottlenecks (temporary, drastic reductions in population size and therefore genetic variability, caused by earthquakes or disease, for example) and a limited ancestral gene pool (Foley 1994; Manica et al. 2007). Studies of genetic variation reveal that the greatest diversity can be found in African populations. This combined with evidence from female (mitochondrial DNA) and male (Y chromosome) specific histories confirms an African origin for our species and suggests our ancestors migrated out of Africa about 70–40 ka (Cann et al. 1987).

In addition to helping researchers identify phylogeny, demographic history, and dispersal patterns, we can also identify areas of the human genome influenced by natural selection. Functional genes, such as those involved in infectious disease resistance; life history patterns; diet; skin, hair, and eye coloration; human cognition; and even language, have revealed areas of the genome that have been influenced by natural selection in humans (Enard et al. 2002; Tishkoff and Williams 2002; Lao et al. 2007; Preuss 2012).

Key Issues/Current Debates

The contemporary science of human evolution is an interdisciplinary endeavor encompassing anatomy, anthropology, archaeology, botany, climate sciences, ecology, genetics including ancient DNA studies and geogenomics, geology, history, linguistics, paleoanthropology, paleontology with related subdisciplines, phylogeny, physiology, primatology, and a number of different disciplines specializing in dating. All these disciplines contribute with data and interpretations. They are also, however, contributing to making human evolutionary studies a theoretically heterodox

field. One of the main challenges, therefore, is to correlate data and results from different fields, while managing the differences in perspectives and theoretical traditions.

The increasing theoretical and practical complexity and the abundance of new data have overturned a number of simple scenarios of human evolution, leaving a far more multifaceted understanding of the past 6–7 million years of the human story. This aspect has had a great impact on the key questions in human evolution. Traditionally, in classic studies from the late nineteenth and early twentieth centuries, the main events could be summarized to terrestriality, bipedalism, encephalization, and civilization. Opinion was divided as to the order and importance of these key events, but the general consensus was that understanding what really happened in human evolution depended upon solving these four questions.

Following the increased theoretical complexity, the number of key questions has multiplied and now involves a thorough interdisciplinary understanding of the evolution and functions of adaptation, behavior, bipedalism, brain size, chronology, climate, common descent, evolutionary constraints, culture, dispersal and migration, diet, diversity, ecosystems, extinction, genetics, geography, language, lineage, morphology, ontogeny, phylogeny, species concept, technology, and variation. The answer to these questions includes a number of theoretical assumptions about time, selection pressures and mechanisms, inheritance, speciation, convergence, continuity, and discontinuity.

Take, for example, our changing perception of *Homo habilis* (dating between 2.1 and 1.5 Ma). First identified at Olduvai Gorge in Tanzania by Mary and Louis Leakey in the mid-1960s in the same general area as Oldowan stone tools, this was classified as the earliest member of the *Homo* lineage. Specifically, its name means, "man the handyman." In the 1960s, the existing evidence base and predominant view that tool making was unique to the *Homo* genus was a key factor in how these fossils were classified. In addition to tool use, *habilis* had more "modern" (derived) characteristics, including a relatively larger cranial capacity (680 cm^3), weaker brow ridges, smaller teeth, a higher forehead, and postcranial fossils, suggesting beyond doubt that it was fully bipedal. The reduction in so-called ancestral characteristics tipped the balance and led paleoanthropologists to classify it as *Homo*.

Since the 1960s however, more fossil and archaeological evidences have raised doubts about handyman's place in the hominin family tree. New evidence shows that *Australopithecus afarensis* was already using stone tools at 3.4 Ma more than a million years before *habilis* existed. It is also clear that tool making is ubiquitous across the primate order and not confined to *Homo* (Bentley-Condit and Smith 2010; McGrew 2010). Taken alone handyman's characteristics such as the larger brain and smaller teeth were deemed to be more derived traits. However, as more australopithecine species (especially *Au. garhi*) were discovered, the overall body size and shape, locomotion, the masticatory system, and dental wear analyses suggested that *habilis* had an adaptive strategy more similar to australopithecines than later *Homo* (Kuykendall 2003). For these reasons, some paleoanthropologists argue that *Homo habilis* should indeed be *Australopithecus habilis*. Whether or not this is valid depends not only on the fossil evidence, but how a genus is defined and whether phylogeny (evolutionary relationships) should be given precedence over adaptive strategies when defining a genus (Wood 2009; Arsuaga 2010).

As the transdisciplinary evidence base expands, it is not uncommon for (phylogenetic) models to change and whether we assign *habilis* to the genus *Homo* or *Australopithecus* has far-reaching effects in our interpretation of the fossil record as a whole. Indeed a similar debate surrounds the classification of chimpanzees, with some primatologists and geneticists arguing that *Pan* and *Homo* should be considered subgenera of *Homo* (e.g., *Homo homo sapiens* and *Homo pan troglodytes*) on the basis of how we interpret the fossil, archaeological, genetic, and behavioral evidence (Goodman et al. 1998; Aiello and Andrews 2000)

The specific nature of data, evidence produced within specific disciplinary frameworks, and the

consequences of using different methods and evolutionary models thus shape our interpretation of the evolutionary evidence.

Role of Theory

Theory has played a central role in the development of our understanding of hominin evolution. By creating theories based on the then current evidence, new sources of evidence can be found with which to test the existing theories. Environmental pressures have long been assumed to play a key role in hominin speciation and adaptation (Maslin and Christensen 2007). The *savannah hypothesis* implicates the long-term trend toward increased aridity and the expansion of the savannah as a major driver of hominin evolution. As opposed to long-term directional trends, the *variability selection hypothesis* advocates the role of environmental unpredictability in selecting for behavioral or ecological flexibility (Potts 1998). However, these hypotheses, which emphasize long-term trends toward either a drier or more variable climate, do not explain the pulsed nature of hominin speciation and migration events. Two alternative hypotheses, however, try to account for the discrete and episodic nature of hominin evolutionary events. The *turnover pulse hypothesis*, developed to explain discrete patterns in ungulate speciation, suggests that acute climate shifts drive adaptation and speciation (Vrba 1988). However, the evidence for this hypothesis is equivocal as the stacked benthic foraminifera $\delta^{18}O$ record, which is thought to represent global climate, does not contain the temporal signatures associated with key events in hominin evolution. A region specific hypothesis, the *pulsed climate variability hypothesis*, highlights the role of extreme wet-dry climate cycles specific to East Africa in driving hominin evolution (Maslin and Trauth 2009).

This last hypothesis is based on the distinct geologic and climate conditions of East Africa. The East African Rift System (EARS), one of the most extensive geological features on the Earth's surface, runs north–south for around 4,500 km from Syria through East Africa to Mozambique. The formation of the EARS had a profound effect on the long-term climate of East Africa. Evidence from carbon isotope records from both soil carbonates (Fig. 3) and biomarkers (*n*-alkanes) extracted from deep-sea sediments provide clear evidence of a progressive vegetation shift from C3 (~trees and shrubs) to C4 (~tropical grasses) plants during the Plio-Pleistocene. This shift has been ascribed to increased aridity due to the orographic barrier produced by the progressive rifting of East Africa during this period and supports the savannah hypothesis, which attempts to explain the appearance of bipedalism.

The progressive formation of the EARS also led to the production of isolated basins within which lakes could form (Fig. 3). Southward propagation of rifting and magmatic activity resulted in the formation of lake basins first in the northern parts of the EARS. For example, fluviolacustrine history of the Afar, Omo-Turkana, and Baringo-Bogoria Basins in the north began in the Middle and Late Miocene, whereas the oldest lacustrine sequences in the central and southern segments of the rift in Kenya and Tanzania are found in the Early Pliocene. Despite the southward progression of tectonic processes in East Africa, ephemeral deep-water lakes seem to occur in separate basins at approximately the same time, suggesting a climatic control (Maslin and Trauth 2009). There is growing evidence that during each of these major lake phases, the large fresh-water lakes appeared and disappeared on a precessional timescale, and is associated with repeated periods of extremely wet and arid conditions within the EARS (Fig. 4). Up to and including 2.6 Ma, these lakes track 400 ka eccentricity cycles. Subsequently, these lake phases still occur at the peak eccentricity forcing but only at 1.8 Ma and 1.0 Ma, with the most significant lake phase at 1.9–1.7 Ma, corresponding with the intensification of the Walker circulation (Trauth et al. 2005). At this time, the E-W sea surface temperature gradients in both the Pacific and Indian Oceans increased intensifying the E-W moisture transport in the tropics, which greatly increased rainfall variability both on a precession and an ENSO (El Niño Southern Oscillation) timescale. The best example of the *pulsed climate variability hypothesis* is the most profound period of

Human Evolution: Theory and Progress, Fig. 3 Environmental context of human evolution in Africa. Comparison of eccentricity variations (*a*) with global climate change (*b*), high latitude climate variations (*c*) with East African lake occurrence (*d*), Mediterranean dust flux (*e*), Soil carbonate carbon isotopes (*f*), with Hominin Evolution Transitions (*g*). (Adapted from Trauth et al. (2007))

hominin evolution at about 1.9 Ma; when there is the highest recorded diversity of hominin species, *Homo (sensu stricto)* appears with brain expansion of up to 80% and migration out of East Africa into Eurasia occurs for the first time. During this key period, ephemeral deep-fresh-water lakes appeared along the whole length of the EARS, fundamentally changing the local environment. However, it must be stressed that this theory is just one of many in a long history and the more paleoclimate and paleoanthropological data is collected, the theories will continue to evolve.

Environmental theories however can only go so far to explaining why some species thrived and managed to migrate across the globe. The application of environmental determinism should be done with great care especially with hominins for whom at some stage 'social' attributes and behaviours may have influenced morphological evolution. Insights into hominin behavior, mate choice, parental investment, foraging behaviors, and social cooperations which come from the behavioral sciences are thus essential to understand the full range of human evolution. Anthropology, behavioral ecology, economics, primatology, and neuroscience tell us that human life history has evolved gradually, humans are highly cooperative, and reproduction is communal (Tooby and DeVore 1987; Boyd and Richerson 2005).

Human Evolution: Theory and Progress, Fig. 4 Three theoretical models of possible lake changes in East Africa during the Plio-Pleistocene and their implications for the causes of human evolution. 4e Model 1 suggests that there is a relatively smooth and gradual transition between periods with deep lakes and periods without lakes. If this "smooth" model is correct, there may have been prolonged periods of wet or arid conditions, which may invoke the Red Queen Hypothesis or the Turnover Pulse Hypothesis (*TPH*) as possible causes of evolution. Red Queen Hypothesis suggests that continued adaptation is needed in order for a species to maintain its relative fitness among co-evolving systems and that biotic interactions rather than climate are the driving evolutionary forces. While the extreme dry periods would support the TPH which suggests that during arid conditions, selective evolution toward larger, more juvenilized descendants in the bovid lineages and hominins would have occurred. Model 2 envisages a "threshold" scenario whereby ephemeral lakes expand and contract extremely rapidly, producing the very rapid onset of extremely dry conditions required by deMenocal's (1995) "aridity hypothesis." Model 3 is an elaboration of the threshold model in which there is "extreme climate variability" during the rapid transition between deep-lake and no-lake states. Such a model would invoke extreme short-term variability that could drive speciation and extinction events, especially if this climate change occurred over a large geographic region. This would produce the widespread environmental variability as required by the "Variability Selection Hypothesis" of human evolution

International Perspectives

Evidence for human evolution is scattered far and wide. The record is certainly not complete overall, but nor is it completely poor. In locations such as the Turkana Basin in east Africa (*Australopithecus, Paranthropus, Homo*), Atapuerca in Spain (*H. antecessor*), and the recent finds on the Indonesian island of Flores (*H. floresiensis*), researchers have collected abundant amounts of fossils and constructed a very in-depth local record. To see human evolution across deep timescales of millions of years however, it is essential to combine multi- and transdisciplinary evidence from all over the world. An excellent example of evidence coming together from all parts of the world is illustrated by evidence for an adaptive shift with *Homo* at around 2 Ma.

This major adaptive shift coincides with *Homo erectus* (1.8 Ma–300 Ka) and we now know that in addition to significant increases in brain size, changes in body shape (relatively elongated legs and shorter arms) which indicated a loss of tree climbing adaptations, innovations in tool technology (earliest handaxes), an ability to walk and possibly run long distances, *H. erectus* had a growth rate similar to that of a great ape with delayed juvenile development, indicating extended periods of learning as well as evidence for care of elderly and weak. They were also the first globetrotters, dispersing beyond Africa, across the Middle East and into Asia (Fig. 5).

However, when *H. erectus* was first unearthed in the form of a skull cap by Eugene Dubois in 1891 in Indonesia, it was the most primitive and smallest brained of all known early human species. This long skull, with a flat forehead, distinct browridges, and saggital keel, was initially placed in a separate genus. Not until the 1950s, by which time many more fossils were uncovered, was it placed into the *Homo* genus. Further discoveries of similar skull caps were made in Zhoukoudian in China and they were initially clearly confined to Asia. It explains the importance of taking the

Human Evolution: Theory and Progress, Fig. 5 Dates and location of early *Homo erectus* finds

historical context of fossil finds into consideration. At the time, these early fossils were the most primitive known with only Neanderthal specimens in Europe for comparison until the 1920s and 1930s when *H. heidelbergensis*, *Australopithecus africanus*, and *Paranthropus* discoveries started to hint that the human family tree was more complex.

The fact that we now associate *erectus* with a major shift in the adaptive complex from earlier Australopithecines shown in cranial and dental morphology, behavior, and technology would perhaps startle earlier paleontologists (Wood and Collard 1999; Foley 2002). It demonstrates that human evolution is neither the result of a single revolutionary event nor a smooth accumulation of increasingly modern human features. Instead it is a cumulative process, with novel adaptations arising and disappearing in response to environmental pressures.

A lot more information about erectus body size, shape, and growth patterns came to light in 1984 with the discovery of the Turkana Boy from Kenya. Dated to 1.6 Ma, this near-complete skeleton (sometimes assigned to *Homo ergaster*, it is typically described as the "African erectus") of an 8-year-old male standing relatively tall at 1.60 m suggested that *H. erectus* was not nearly as primitive as previously thought (Fig. 6). A large cranial capacity (880 cm^3 compared to 1,300 cm^3 in modern humans) and tall stature illustrated a dependence on bipedalism, a growing rate (and probable adolescent growth spurt) similar to modern humans. The Turkana Boy made it clear that *H.erectus* originated and persisted in East Africa but left many questions on how, why, and when this species was able to disperse widely not only across Africa, but also in China and Java by 1.8 Ma, though it should be noted that this date is continually revised and it may have occurred slightly later. Evidence is now available from a plethora of fields and provides a solid empirical base to describe and explain the life course of this versatile, global traveler.

H. erectus thrived in a period of major climate change. Combining data from carbon isotope records from soil carbonates and biomarkers extracted from deep-sea sediments, paleo-geologists, -chemists, and physicists have put together a paleo-environmental model which

Human Evolution: Theory and Progress, Fig. 6 Comparison of *Homo erectus* skulls of Turkana boy (Kenya) and Peking man (China)

illustrates a progressive vegetation shift form C3 (trees and shrubs) to C4 (tropical grasses) plants during the Plio-Pleistocene. Previously semiarid areas became moister with denser vegetation and more lakes (King and Bailey 2006), making it easier for *H. erectus* to migrate from East Africa into Asia via the "Levant Corridor" through northeast Egypt, Israel, Lebanon, Syria, and Turkey.

In addition to teams from across the world comparing fossil evidence and compiling an environmental narrative in which *H. erectus* evolved, anatomists, primatologists, and ecologists were bringing in their own theoretical paradigms to build up a picture of how *H. erectus* would have survived. Since body size influences a range of physiological traits including energy requirements, choice of food, reproductive strategies, predation risk, range, and locomotor style, paleoanthropologists can learn a lot by comparing *H. erectus* specimens to those of living species. Estimates suggest that *H. erectus* specimens would have been 50% heavier than australopithecine females. The consequent energetic costs of reproduction, which can be extrapolated based on what we know of human and chimpanzee females, suggest that daily energetic requirements of gestation and lactation would have been significantly higher for erectus females (Aiello and Key 2012). Human biologists suggest that shortening the inter-birth interval would reduce these costs and increase reproductive output. These changes in life history will have necessitated changes in behavior, for example, increased cooperation and the division of labor. An ability to do so may have been facilitated by language, and evidence from the cervical vertebrae of *H. erectus* fossils from Dmanisi in Georgia shows that they are well within the normal human range, illustrating that erectus was probably able to regulate its breathing and produce complex sounds.

Another way to meet energetic requirements would be to eat energy-dense foods such as meat and technology advances such as the hand ax would have aided *H. erectus* in procuring such foods. The earliest evidence for fire is also associated with erectus fossils, this is significant because cooking food increases the energy availability in foods (Carmody and Wrangham 2009). Alternatively, you could offset the cost of metabolically expensive tissues, such as the brain, with a reduction in energetic cost somewhere else. The so-called expensive tissue hypothesis is based on comparing gut size across mammals. Anatomists have shown that gut size is highly correlated to diet and shown that the human gut is significantly smaller than expected for an animal of our body size. The expensive tissue hypothesis argues that we have managed to cut energetic costs by reducing gut size because species like *H. erectus* made the move toward hunting or scavenging high-energy and easily digestible meat products (in comparison to plant materials). This allowed an energetic cost saving by reducing the gut size which no longer needed to work so hard. Combining anthropological observations of the Hadza, traditional foragers in Tanzania, with evidence for the erectus' climate-driven adjustments in female foraging and food sharing practices, and longer lifespans, others argue that new social behaviors, such as grandmothers taking care of daughter's offspring, allowed *erectus* to thrive (O'Connell et al. 1999).

Using transdisciplinary evidence from paleoanthropology and primatology to anatomy and biology in combination with the fossil evidence from across the globe, we are now in a position to grasp anatomical, behavioral, and cognitive shifts that accompany the Plio-pleistocene hominins.

Future Directions

There are exciting developments in all fields that are contributing to the understanding of human evolution. We are increasing our understanding of the fossil record and must be prepared for additional surprises such as the discovery of *Homo floresiensis*. In the field of paleoclimate, we understand more and more about the landscape in which our ancestors evolved and how variable it may have been. In the last few years, of all the new fields, genetics has probably had the biggest impact on human evolutionary studies. However, if anything has been learnt from the past, it is that

our understanding of human evolution can only occur by combining evidence from multiple fields of study. This way, new theories can be developed and then tested with evidence.

Human Evolution: Use of Fire

John A. J. Gowlett
Archaeology, Classics and Egyptology, School of Histories and Cultures, University of Liverpool, Liverpool, UK

Introduction

Fire is a resource of nature that has been harnessed by humans in their technology in such a wide-ranging and far-reaching way that it must be seen as a force in the evolutionary shaping of humanity. Fire use is difficult to investigate because in most cases it leads to no definite artifact, and most of its traces are easily lost to erosion and decay. Nevertheless, traces of burning are known from a surprisingly high number of early sites, and there is no doubt in some cases that they record fire use under human control.

Definition

Fire in Nature

Fire is a natural resource widespread in nature. Although it can be created by volcanoes, friction, or spontaneous combustion of matted vegetation, most of it is created by the many thousands of lightning strikes which occur each year. Thunder storms occur most intensively in the tropics and least commonly towards the Arctic Circle, but the highest "take-up" in bushfires and forest fires occurs in the subtropical semiarid zones and in temperate forests. Fires occur seasonally, often starting when the first lightning of an early season storm comes ahead of the main rainfall. "Fire weather" is well known in some regions and has generated its own literature in forestry research. Although some authors regard fire use as requiring advanced cognition, many animals, especially birds, make use of it in "fire following." Bush fires expose or drive prey in the form of insects, birds, nests of eggs, lizards, and small mammals, as well as revealing or cooking plant resources such as roots. Animals are often less disturbed by fire than

implied by classic stories such as Kipling's Jungle Book, and recently, savanna chimpanzees have been observed to show a situation awareness of fire's behavior.

Key Issues/Current Debates/Future Directions/Examples

Patterns of Human Fire Use

Human fire use can be set in three broad categories. First, opportunistic – a simple fire following geared to harnessing the most obvious resources; second, tethered, where fires are kept burning and perhaps moved to favored localities; and third, kindled or mastered fire, in which fire can be made and used at will. Of course these are arbitrary categories, not a necessary universal progression. Sometimes, they might be used side by side, and people (such as the San in southern Africa) who know how to kindle fire might prefer to operate via tethered fire, either because of religious prohibitions or for ease. The Hadza in East Africa sometimes keep the same fire burning for months at a time. Animal dung provides a convenient slow-burning material for tapers and is easily transportable. Australian aborigines have sometimes been known as "fire stick farmers" because they use selective burning to manage resources on the landscape. The ability to kindle fire greatly increases the flexibility of fire use, and the skills involved demonstrate advanced cognitive capacities, particularly the knowledge that something entirely new (fire) can be released from materials which are not burning at all. Before the invention of modern means, fire was generally made by striking selected stones together and catching the spark on prepared tinder or, by friction, using hard and soft wood. Greater rotational speed could be given to a fire drill by the use of a bow and string. The earliest shell beads with pierced holes suggest that cord was in use at least 100,000 years ago, but use in fire-making is not directly attested until the last few thousand years.

The Earliest Fire in Africa

The oldest archaeological evidence for fire comes from three sites in East Africa – Koobi Fora, Chesowanja, and Gadeb. All have burnt material in close conjunction with archaeological finds. At Chesowanja, burnt clay was found in a concentrated series of lumps among artifacts. At Koobi Fora, patches of burn sediment were found. The associations have been doubted on "taphonomic" grounds, but the doubt is not in the physical association but in the lack of necessary causal connection between the burnt material and the artifacts. The burnt patches could come from natural fires, and the artifacts are not specifically tied to fire use.

In southern Africa, the most valuable evidence comes from the cave sites of Swartkrans and Wonderwerk. At Swartkrans in Member 3, burnt bone has been found in numerous places and layers. At Wonderwerk, there is extensive evidence of charcoal fragments in one layer, and microanalysis tends to rule out bush fires. Claims of dates greater than one million years are not fully substantiated for these sites, but they certainly date to at least 800,000 and together demonstrate early human fire use with near-certainty.

Somewhat later is the Acheulean site of Kalambo Falls in Zambia. There, the late Desmond Clark excavated numbers of charred wooden artifacts, and a probable hearth was found. The site could be as old as 400,000 years.

The Earliest Fire in Eurasia

In Asia, charred bone was found at Bogatyri north of the Black Sea dating to 900,000, but the best known site with fire evidence is Gesher Benot Ya'aqov in Israel, dating to about 700,000. Here, charred plant material has been found from multiple levels and also "ghost hearths" marked out by tiny fragments of burnt flint. Part of the case for human control is the repeated nature of the burning in a lakeside context. Natural fire caused by lightning tends to occur spasmodically and usually on exposed slopes. Also well known is the cave of Zhoukoudian in China, where fire evidence has been recognized since the 1920s but remains controversial. Although some dark material has been shown not to be charred, but mineral stained, burnt bone is testified from the site at about 500,000 years.

Western Europe has provided some of the most convincing evidence for early fire use within the last half-million years. Beeches Pit in eastern

England dates to the Hoxnian interglacial at about 400,000. Here, there is a series of hearths. Beside one of them, an individual knapped a flint hand ax, and two of the series of 30 pieces which can be refitted fell forward into the hearth area and became burnt bright red. The knapping provides a direct connection with the fire, and the extreme selectivity of the burning disproves the idea of any wider natural fire. Again, as at Gesher Benot Ya'aqov, the site is by the side of water. Similarly, at Schoningen in Germany, of similar age and very well known for its preserved wooden spears, hearths are preserved, and in one a wooden stave found that is part-burnt. It may have been used as a hand-spit for roasting meat. Again, the direct association of burnt artifact and hearth provides incontrovertible evidence of the human context.

In the last 200,000–300,000 years, evidence of fire use becomes much more common. Many caves have sequences of hearths, for example, et Tabun in Israel or Bolomor in Spain. Bolomor is interesting, because it shows Neanderthals making small fires for cooking small animals such as rabbits. Elsewhere, such as Abric Romani in Spain or the earlier Beeches Pit, fires were large, more than a meter across. They may have been used for cooking larger animals such as pig or deer, and their fuelling implies some division of labor. Neanderthals certainly achieved a high degree of fire control. At Königsaue in Germany, they prepared pitch from resin, which can only be done by keeping high temperatures over a long period. In Israel, Middle Paleolithic people learned to fire gypsum plaster. In both cases, the material can be used to fix a stone tip to a wooden haft. It is notable that in several of our earliest cases of fire use, there is a link between the fire and fireside technology.

Hypotheses About Fire

Archaeology has the task of testing the balance between two different perspectives on fire use. The first of these is a general modelling view, taking into account biological, ecological, and psychological disciplines. It argues that human fire use began at an early stage, probably around the time of the first brain expansion in *Homo*, and that it played a major role in changing diet. The second view is much more cautious, depending on the fire evidence actually preserved on archaeological sites, and requiring definite traces of hearths or other burning of artifacts as its primary evidence. The philosophies of these approaches are different, although they can grade into one another. They leave us with views that fire use began as early as 1.7 million years ago or as late as 400,000 years ago. But considering that there can be different grades and types of fire use, the results could be less incompatible than they appear.

The cooking hypothesis has been championed by Richard Wrangham and colleagues.

Early hominin ancestors living in environments where fruit sources were limited would require access to other carbohydrates, as in roots. But starch is indigestible, and greater inputs of meat also require predigestion for a creature without an ancestral history of carnivory. Archaeological evidence does not prove that cooking provided the answers, but the general case and the regular association of burnt material with archaeological sites is strongly suggestive. The greatest puzzle is lack of fire evidence in the north, where fire would be most desirable – but also least available from nature. African cave sites have fire evidence, but so far, early European cave sites such as Arago do not, although humans were present and butchering animals. Possibly at this stage, fire was used only in particular places on landscapes.

It can remain hard to distinguish natural fire and human fire in the past record, because their patterns often overlap. Temperature of burning is not a good indicator – both natural and controlled fires will frequently burnt in the range 200–600 °C – but repeated burning in one place strongly indicates human use. Hearths provide good evidence but can sometimes be mimicked by natural features. Microscopic thin section studies can help to distinguish the type of burning. Selective burning of artifacts provides the strongest evidence for human control.

The Role of Fire

How important was fire in human evolution? Arguably, it was one of the most crucial technologies, raising the quality of diet and so helping

humans to acquire and maintain the large and expensive brains that had such great social implications. Once set in hearths, fire was also the focus of both social and technical activity. It allowed humans to gain a longer day and to alter their circadian rhythm so that they are awake more hours per day than other animals. Our peak alertness is in the early evening, when the apes are retiring to bed. The additional hours could be used for preparing food, making or repairing tools, or simply in conversation. Many technologies depend on fire, combined with time, patience, and skill. Apart from the pitch and gypsum already mentioned, one early use was the warming of stones so that they were more tractable for knapping, a practice observed at Pinnacle Point cave in South Africa about 120,000 years ago. Other uses of fire have multiplied greatly in recent times – in the late Paleolithic of France, water in small pits was heated by "pot boiler" stones for cooking; in the Upper Paleolithic of Moravia, small clay animal figures were baked; and in the Far East, true pottery goes back at least 20,000 years. Open fires have a temperature limit of about 800° centigrade. Within the last 5000 years controlled drafts were introduced, allowing temperatures to be greatly raised. Smelting of metals and production of glazes and glasses were among the results.

Human Impacts on Ancient Marine Ecosystems

Torben C. Rick[1] and Jon M. Erlandson[2]
[1]Department of Anthropology, National Museum of Natural History, Smithsonian Institution, Washington, DC, USA
[2]Museum of Natural and Cultural History, University of Oregon, Eugene, OR, USA

Brief Definition of the Topic

Understanding human impacts on ancient marine ecosystems is an area of archaeological research focused on the interactions between ancient peoples and marine environments and organisms. Closely allied with historical ecology (Crumley 1994), studies of human impacts on ancient marine ecosystems are interdisciplinary, drawing on history, biology, paleobiology, and other fields. This research is being performed by scholars around the world on a variety of different ecosystems (coral reefs, kelp forests, estuaries, etc.) and focused on different scales of human economic and social organization (e.g., hunter-gatherers, maritime agriculturalists, and states). The toolkit used to investigate this topic is equally diverse, relying on zooarchaeology, stable isotope analyses, ancient genetics, and geoarchaeology. Coastal archaeological and historical ecological studies are providing important deeper context for contemporary environmental problems and ecological restoration and conservation.

In studying human impacts on ancient marine ecosystems, researchers have focused on several key questions. When did people first settle along a particular coastline? What was the nature of ancient human subsistence economies in coastal areas, and how did these vary across space and through time? Did people have an impact on marine resources or ecosystems in the past, or is there evidence for long-term sustainability? What can ancient human interactions with and impacts on marine ecosystems tell us about contemporary environmental problems facing the ocean?

From North America's Pacific and Atlantic coasts to the North Sea, tropical Pacific and Caribbean islands, Mediterranean, Africa, and beyond, ancient peoples settled along the coast in the distant past. Humans have harvested coastal resources for more than 150,000 years in southern Africa, and ancient human dispersals to Australia, Pacific and Caribbean islands, and beyond crossed hundreds or even thousands of kilometers of open ocean. Along with natural climatic and other environmental changes, ancient peoples often had an impact or influence on local marine ecosystems – some extending back tens of thousands of years. These impacts vary considerably through time and across space. In some cases, archaeologists are just beginning to understand the patterns and processes of human over-exploitation of marine resources versus cases of long-term and potentially sustainable harvest of coastal ecosystems. Examples of ancient human impacts on marine organisms and ecosystems include the following: (1) resource depression or over-exploitation of key species, including seals, sea lions, and sea otters and shellfish, finfish, and seabirds, (2) predation pressure that results in a decline in the size and/or change in the age structure of marine shellfish and vertebrate populations,

and (3) human-induced trophic cascades, where exploitation of one or more keystone species can result in cascading changes to the structure and function of an ecosystem.

Archaeologists have gathered substantial evidence that many ancient peoples, including hunter-gatherers and agriculturalists, had a strong impact on marine ecosystems, but there is also growing evidence that some ancient peoples harvested resources sustainably over the long-term. Some marine ecosystems appear to be relatively resilient – able to withstand human exploitation while retaining the same basic structure – to certain thresholds of human harvest. In some cases, people also actively enhanced the productivity of specific marine ecosystems or organisms. These include cases of ancient aquaculture in Asia, Europe, North America, and the Pacific Islands, where engineering of streams and other waterways was used to create or enhance fish ponds, as well as the "clam gardens" of the Pacific Northwest (e.g., Lepofsky et al. 2015).

More recently, archaeologists have used data on ancient human impacts on marine ecosystems to help inform the management, restoration, and conservation of modern marine ecosystems, fisheries, and organisms. Today, the world's oceans are rapidly being degraded by human activities such as over-fishing, nutrient over-enrichment, pollution, wetland destruction, climate change, and invasive species introductions. Archaeological data provide important baselines and deep historical context on how marine ecosystems have changed over centuries or millennia, with and without human influence. When placed in the context of historical, paleobiological, and modern records of the long-term natural and anthropogenic influences on marine ecosystems, archaeology is a powerful tool for helping better understand contemporary environmental problems.

Coastal archaeology and research on human impacts on ancient marine ecosystems is also contributing to broad scientific discussions about the Anthropocene, or Age of Humans. There is considerable debate about when the Anthropocene began (~13,000 years ago or perhaps as recently as 50 years ago), with one proposal that Late Pleistocene/Holocene shell middens may be a stratigraphic marker for the onset of this new geological time period (Erlandson 2013).

Today, coastal archaeological sites around the world are increasingly threatened by accelerated sea level rise and erosion, development and construction projects, looting, and many other processes. As research into human impacts on ancient marine ecosystems continues to grow, we also need to work to conserve the fragile and disappearing global coastal archaeological record that is the foundation for this research.

Human Migration: Bioarchaeological Approaches

David C. Meiggs[1] and Carolyn Freiwald[2]
[1]Department of Sociology and Anthropology, Rochester Institute of Technology, Rochester, NY, USA
[2]Department of Sociology and Anthropology, University of Mississippi, Oxford, MS, USA

Introduction

Migration is one of oldest and most widespread characteristics of humanity and identifying it in the past is one of the most critical questions that archaeologists address. Migration affects nearly every aspect of life, from the availability of sufficient land, food, or marriage partners, to the spread of deadly diseases. Archaeologists traditionally recognize ancient societies using material objects, which is problematic for research on migration. When does a change in material culture represent an influx of new people into a region, and when is it only trade or new ideas? The most critical changes in human history, like the transition from hunting and gathering to farming, hinge on this question. Significant advances in answering some of the most important questions in human history have come from a renewed interest in studying migration and development of new methods using bone chemistry and DNA (cf. Hakenbeck 2008).

Bioarchaeological methods are an important part of research on human mobility and provide a unique set of data that are otherwise not available. For example, analysis of seasonal and geographic movement of livestock at large urban centers can provide information on a society's perception of its environment, economy, and social organization. The precise "origin" of the animals matters less than how patterns might differ between house compounds, quarters of the city, and so-called market areas. The questions archaeologists ask about ancient mobility are diverse, and the number of scientific approaches they are using continues to grow (e.g., Cabana and Clark 2011; Cucina 2014; van Dommelen 2014; Kaiser et al. 2012). This entry focuses on the use of DNA, isotopic and elemental analyses, and osteological approaches to understanding ancient mobility.

Definitions

The term "bioarchaeology" is not limited to human skeletal remains, but can refer to all fauna recovered from an archaeological site. A bioarchaeological approach implies a suite of anthropological research questions and is not limited to a specific analytical technique. In North America, bioarchaeology is a multidisciplinary research strategy that focuses on human remains to reconstruct life histories and population structure (Buikstra and Beck 2006; Buikstra 1977; Larsen 2002). However, human skeletal remains do not represent the full range of materials archaeologists are using globally to investigate migration in past societies. Analyses may also include population genetics of modern peoples and archaeological fauna as proxies for human mobility.

What *is* migration and how do archaeologists attempt to identify it? Archaeologists have traditionally focused on one-way, long distance movements where one group colonizes a new area, whether uninhabited or by displacement of earlier inhabitants (e.g., Rouse 1986). Human mobility is far more complex, however, and this limited perspective excludes most types of population movement throughout history (Anthony 1990). Individuals or groups may change residence

seasonally to herd livestock. Or individuals may relocate multiple times during their lives, either within a political entity or across a regional or national boundary. Relocation may also be involuntary, as in the case of the slave trade (see contributions in Chapman and Hamerow 1997). Migration includes each of these types of movement, as neither the distance nor the reason for the move form critical parts of the definition.

Historical Background

Diffusionism provided the initial framework that archaeologists used to explain cultural evolution. During the late nineteenth and early twentieth centuries, scholars used migration to explain social change by making a direct connection between changes in artifact styles and ethnically distinct people (Trigger 2006). At the same time, studies of human skeletal variability relied on racial typologies, with migration and admixture figuring prominently in the influential work of Hrdlička and Hooton (Cook 2006; Armelagos and van Gerven 2003).

During the 1960s, the theoretical and methodological shift of processual archaeology seriously challenged the role of migration (and invasion) as an explanation for past sociocultural change (Binford 1968) and decoupled the simplistic link between artifacts and people (Washburn 1953). The emergence of a biocultural approach to analysis of human skeletal remains reflected these trends, explicitly incorporating population movement and relatedness (Buikstra 1977). But processual archaeology marginalized migration as an explanatory framework (Adams et al. 1978), and it only re-emerged in the 1980s (Binford 1980; Anthony 1990). Useful surveys of migration in archaeological explanation and the emergence of the bioarchaeological approach are found in Trigger (2006), Härke (1998), and contributions to Chapman and Hamerow (1997).

Research focuses not only on reconstructing patterns of population movement, but on how mobility articulates with social organization and identity (e.g., Knudson and Stojanowski 2009). Archaeological analyses used to reconstruct human mobility fall into three general categories (Table 1). None of these techniques provide simple "answers" about mobility or relationships between past peoples because each method incorporates assumptions that may result in more than one possible explanation. Archaeologists cannot

Human Migration: Bioarchaeological Approaches, Table 1 Types of analysis used to infer migration in bioarchaeology

Category	Techniques	Evidence for mobility
Osteological	• Biodistance – Cranial (including dental) and postcranial metric and nonmetric systematic variation	• Genetic relationships • Regional variation in cranial or dental modification/decoration
Biogeochemical	• Isotope ratios – Strontium ($^{87}Sr/^{86}Sr$) – Oxygen ($\delta^{18}O$) – Lead (^{204}Pb, ^{206}Pb, ^{207}Pb, and ^{208}Pb) – Sulfur ($\delta^{34}S$) – Carbon ($\delta^{13}C$) – Nitrogen ($\delta^{15}N$) • Trace element ratios – Sr/Ca, Ba/Ca	• Isotope values vary in water, rocks, and soils of different regions. Isotope ratios of Sr, O, Pb, and S track mobility. • Diets may vary regionally, and ratios of C, N, and S reflect different plants and proteins in the diet that may reveal migration. Ratios of elements may vary by region.
Genetic	• Mitochondrial (mtDNA) or nuclear (nDNA) sequences • Polymorphisms in biomolecules other than DNA • ABO blood groups, Rh and HLA antigens • DNA of pathogens	• Identifying haplogroups and historic individuals using ancient DNA (aDNA) • Emergence of new alleles, e.g., lactase persistence (Myles et al. 2005) • The movement of diseases can track movements of people

address mobility in the same ways that modern anthropologists, demographers, and geographers can. Therefore, multiple lines of evidence are fundamental to understanding past human mobility.

Osteological approaches are characterized by macroscopic examination of archaeological human remains (cf. Katzenberg and Saunders 2008) that assess biological and genetic distance among individuals and populations. So-called biodistance distance studies are based on assessment of skeletal metric and/or nonmetric traits. Although current research emphasizes population genetics-based perspectives (Konigsberg 2006; Heathcote 1978), there is some concern that typological (i.e., essentially "racial") approaches persist (Armelagos and van Gerven 2003, but see Stojanowski and Buikstra 2004). Mobility is inferred by deviations from regional variation and has been used to consider gender-specific postmarital residence patterns as well as regional gene flow and interaction (Konigsberg 2006).

Biogeochemical approaches to mobility (e.g., Bentley 2006) take advantage of differences in isotopic signatures in human tissues that reflect systematic environmental variability (Hoefs 2009; Faure and Mensing 2005). Trace element ratios, specifically strontium and barium, also are used to evaluate mobility (Burton et al. 2003). Early analysis of isotopes in archaeological material focused on paleoclimate and dietary reconstruction (e.g., Lee-Thorp 2008; Schoeninger et al. 2000). After Ericson (1985) suggested that strontium isotope ratios ($^{87}Sr/^{86}Sr$) could be used to examine past human residence patterns, it has become one of the most common archaeological biogeochemical techniques. Oxygen isotopes ($\delta^{18}O$), from skeletal carbonate or phosphate, have been also used extensively by archaeologists to identify prehistoric mobility (e.g., Evans et al. 2006). Other isotope systems such as hydrogen, lead, and sulfur also are used to identify migration (e.g., Sharp et al. 2003; Sharpe et al. 2016; Dupras and Schwarcz 2001; Carlson 1996) and multi-isotope applications are becoming increasingly common. Biogeochemical analysis has also been used with archaeozoological material to investigate mobility of pastoralists, as well as strategies used by hunter-gatherers (e.g., Evans et al. 2006; Bocherens et al. 2001; Balasse et al. 2002; Britton et al. 2011).

Genetic techniques were introduced to anthropology in the 1960s (Sarich and Wright 1967), who estimated a last common ancestor between humans and extant primates at just 5 million years ago, shockingly recent according to views at the time. Molecular archaeology emerged as a subdiscipline later, when Cavalli-Sforza et al. (1994) investigated variation in discrete biological factors. For example, allele frequencies such as ABO blood types were visualized geographically. The advent of DNA sequencing and the measurement of mutation rates allowed researchers to add divergence times between populations to this analysis. Cann et al. (1987) used differences in mitochondrial DNA (mtDNA) to suggest an African origin for modern humans c. 100kya. Improvements in technology allow researchers to focus on genetic diversity in modern populations around the globe (Renfrew and Boyle 2000; Cavalli-Sforza et al. 1994; Relethford 1998; Bellwood and Renfrew 2002) and to recover ancient DNA (O'Rourke et al. 2000). A significant milestone was achieved with a draft Neandertal genome (Green et al. 2010), followed by the mapping of many more complete ancient genetic sequences and mutations using smaller amounts of older, more fragmentary aDNA. Improvements to DNA sequencing have been extraordinarily fast, yet the techniques remain time consuming and expensive (Horsburgh 2015). Still, genomic databases continue to grow, as do theoretical limits on how far back aDNA can be recovered. Equally important, diverse ways to use DNA include tracking human migrations via their animals (Larson 2017). Most recently, aDNA of different body tissues such as dental calculus and the commensal bacteria in them adds to the growing body of archaeogenetic information on population differences. Finally, aDNA of pathogens in human tooth and bones is revealing how diseases spread with people around the world.

Using Bioarchaeological Techniques to Reconstruct Migration

Archaeologists attempt to situate evidence of past mobility within a larger contextual framework, but the nature and scale of major research questions varies considerably. At the broadest level are questions concerned with transformational dispersals in human history – from hominins leaving Africa to the spread of agriculture – that frequently utilize genetic analysis to reveal the structure of past human migration and interaction (Underhill and Kivisild 2007). Conversely, the most specific seek to understand how mobility articulates with local or regional social processes of economy, identity, and ritual. Research at this scale involves direct analysis of archaeological skeletal remains and may focus on the life histories of specific individuals. Biogeochemical data at this level only pertain to the period of formation of the sampled skeletal tissue (i.e., period of tooth formation). Table 2 outlines some recent applications of bioarchaeological methods to identify different types of mobility; it is by no means comprehensive but provides some examples of current research.

Bioarchaeological approaches to migration are currently limited by a number of factors. First, most biodistance studies compare morphological traits; however, similarities may result from the environment as well as shared genes. Incomplete skeletal remains also require estimation of missing data and may greatly reduce the sample size, a common problem in archaeological studies. Second, isotope variability does not necessarily correspond to cultural regions, and neighboring and distant regions may display similar ranges. Discussion about the best method to differentiate "local" from "nonlocal" individuals (cf. Price et al. 2002; Burton and Hahn 2016) ranges from statistical methods to complex equations used to map "isoscapes," or the extent of a range of isotope values (Bowen 2010; Wunder 2010). An issue affecting both biogeochemical and genetic analysis is diagenetic alteration in archaeological materials. Increasingly researchers prefer to obtain samples from teeth, as they are less susceptible to alteration in the burial environment (e.g., Trickett et al. 2003). Critiques of early studies involving aDNA also noted the possibility that the results included modern DNA, but next generation sequencing has transformed the field (Hofreiter et al. 2015).

Most studies now combine multiple lines of evidence focused on different aspects of population movement that reveal new and interesting information about topics as diverse as the slave trade, life as a gladiator, or even the mobility of extinct species human ancestors such as Neandertals. One example comes from intensive research on a Neolithic mummy in central Europe using a combination of bioarchaeological techniques to reconstruct the life history of a single individual.

Case Study: The Tyrolean Ice Man

In 1991, hikers discovered a 5200-year-old frozen mummy in the Ötzal Alps. But who was "Ötzi" and where did he come from? The artifacts provided a glimpse into his Copper Age origins, but scientists used isotopic, osteological, and genetic methods to identify Ötzi's homeland and to understand how he lived and how he died.

Where did Ötzi live? Strontium, lead, and oxygen isotope values in his bones and teeth show that he probably spent most of his life less than 60 km from his place of death (Müller et al. 2003). Analyses of his last meals, sampled from his intestinal tract, show that he traveled from lower elevations shortly before he died. Healed rib fractures and skeletal pathologies show that his lifestyle was active, and at times, dangerous (Zur Nedden et al. 1994). It is possible that tattoos on his legs, back, and hands were not simply decoration (Fig. 1), but evidence of therapeutic treatment for his arthritis and other ailments (Renault 2004) and recent high-tech mapping revealed 61 tattoos and their precise placements (Samadelli et al. 2015). Genetic analysis of Ötzi gut bacteria revealed one species that can lead to ulcers or even stomach cancer (Maixner et al. 2016). Sequences of mtDNA even revealed the types of fur used in Ötzi's clothes (cattle, sheep, and goat),

Human Migration: Bioarchaeological Approaches, Table 2 Selected recent bioarchaeological research on migration and mobility

Archaeological questions	Region/locality	Bioarchaeological techniques	References
Dispersal of modern humans	Eurasia	• mtDNA and Y-chromosome • aDNA (nuclear)	(Relethford 1998; Renfrew and Boyle 2000; Weaver and Roseman 2008; Green et al. 2010)
Spread of agriculture	Global	• mtDNA and Y-chromosomes • "classical" genetic markers • $^{87}Sr/^{86}Sr$, $\delta^{18}O$ • Craniometric analysis	(Richards 2003; Bellwood and Renfrew 2002; Ammerman and Cavalli-Sforza 1984; Burger et al. 2007; Haak et al. 2008; Pinhasi and von Cramon-Taubadel 2009)
Peopling of the Americas	East Asia Americas	• Craniometrics • Dental analysis • "Classic" genetic markers • mtDNA & Y-chromosomes	(Pitblado 2011; Schurr 2004)
Pastoral mobility	Eurasia	• $^{87}Sr/^{86}Sr$ • $\delta^{18}O$ • $\delta^{13}C$	(Bocherens et al. 2001; Balasse et al. 2002; Meiggs 2009)
Lifetime mobility	Eastern Mediterranean	• $^{87}Sr/^{86}Sr$ • $\delta^{18}O$	(Mitchell and Millard 2009)
	Imperial Rome		(Killgrove and Montgomery 2016; Lösch et al. 2014; Prowse et al. 2007)
	Bronze age Britain		(Evans et al. 2006)
	Mesoamerica – Maya heartland – Central Mexico	• $^{87}Sr/^{86}Sr$, $\delta^{18}O$, $\delta^{34}S$ • Biodistance analysis	(White et al. 1998; Price et al. 2000; Scherer 2007; Freiwald 2011; Cucina et al. 2017; Scherer and Wright 2015)
Slave trade	Yucatan Barbados South Africa	• $^{87}Sr/^{86}Sr$ • $\delta^{18}O$	(Mbeki et al. 2017; Price et al. 2006; Schroeder 2009)
Sacrificial burial	Mesoamerica South America	• $^{87}Sr/^{86}Sr$ • $\delta^{18}O$	(White et al. 2007; Knudson et al. 2009)
Kinship, postmarital population movement	Neolithic Europe Thailand US southwest	• $^{87}Sr/^{86}Sr$ • $\delta^{18}O$ • aDNA	(Bentley et al. 2007; Haak et al. 2008; Ezzo et al. 1997)
Identity and social hierarchy	Japan South America	• $^{87}Sr/^{86}Sr$ • $\delta^{18}O$ • dental ablation	(Kusaka et al. 2009; Knudson et al. 2017; Turner et al. 2009)
Disease transmission	New and old world "plagues"	• aDNA of humans and pathogens	(Wagner et al. 2014; Vågene et al. 2018)

and his hat and quiver (bear and roe deer) (O'Sullivan et al. 2016).

Who was he? An initial study of Ötzi's paternal genetic heritage linked him to modern populations in the Tyrolean Alps. Later studies tell us that he was blood group O, lactose intolerant, and susceptible to cardiovascular diseases, and most important to our understanding of migration patterns, that genetic heritage links him to modern populations. However, his maternal lineage is not found in later Neolithic or modern populations, revealing previously undiscovered ancient migration and demographic patterns (Coia et al. 2016).

Human Migration: Bioarchaeological Approaches, Fig. 1 Bioarchaeological techniques used to reconstruct Ötzi's life history. (Adapted from Renault 2004)

Was Ötzi a migrant? Ötzi was not far from his place of birth when he died, and the circumstances of his death have prompted speculation that he was fleeing his home. He was wounded in multiple places in the days before his death, including his right hand, but most likely died from blunt force trauma and an arrow wound in his back that appears to have severed an artery (Nerlich et al. 2009).

Another example comes from the life and migration history of the Maya king K'inich Yax K'uk' Mo′ from the Classic period site of Copan in modern day Honduras. Bioarchaeological, isotopic, textual, and archaeological data suggest that he moved multiple times during his life and that his nonlocal origin was an important factor in his role as ruler. Other migrants have been identified at Copan, Tikal, and nearly every Maya site that has been studied to date (Cucina (ed) 2014), which allows researchers to place this study in a broader regional context and to suggest that migration was a common phenomenon in the Maya lowlands (Freiwald 2011).

The 2012 discovery of the grave of King Richard III in England provides the most recent example. His identity was confirmed by osteological analysis of his ailments, including severe scoliosis, and injuries consistent with a death on the battlefield. Recovery of aDNA provided his likely hair and eye color; his mtDNA matched that of a living relative, though his Y-chromosome haplotypes surprisingly ruled out matches with patrilineal family descendants. Isotope geochemistry results, including radiocarbon dating, were compared to historic texts to reveal when and where he lived, and even what he ate and drank (King et al. 2014).

Future Directions

Bioarchaeologists are expanding their collaborations with specialists at the cutting edge of research, from identifying historic individuals to the diseases that affected them. Providing

open-access availability to 3D scans of the skeletal remains for use in printing models of rare *Homo naledi* hominin bones, along with detailed publications and a documentary film, was a leap forward expanding the accessibility to bioarchaeological data. Other researchers followed with "print-your-own" Lucy (*A. afarensis*) skeletal remains. Libraries of printable bone models will make bioarchaeological materials widely available for comparison, although broad discussion about the ethics of what *can* be printed versus what *should* be printed is needed.

Investigation of other isotopes in skeletal material such as calcium or copper may provide new proxies for mobility (Jaouen and Pons 2017), and the use of isotopes other than Sr and O such as sulfur and lead to reconstruct population movement in different geographic regions is providing more baseline data for researchers (e.g., sulfur, Richards et al. 2001; Vika 2009). Predictive models developed for modern forensic studies aimed at finding the points of origin for migrants, missing persons, or genocides, and other conflicts also will prove crucial to archaeological studies of migration in coming years (Bartelink et al. 2014).

Advances in aDNA analysis will prove particularly relevant to understanding not only paleomigration, but its effects on both ancient and modern populations. Identifying pandemic diseases such as influenza and endemic ones such as tuberculosis help to reconstruct demographic histories and understand how the disease and our own immune systems have evolved over time (e.g., Wagner et al. 2014). Isotopic information bears on health matters as well, including studies of ancient lead (Budd et al. 1998). There also is an increasing recognition that no method is atheoretical and that any bioarchaeological data are embedded in questions that orient a particular research project. Ultimately, even the most advanced techniques are limited by the nature of the archaeological record, but the ability of archaeologists to identify past mobility and place it within a larger social context is stronger than ever.

Human Remains from Modern Conflicts, the Archaeological Study of

Amanda Lauren Murphy
University of Manchester (alumna),
Manchester, UK

Introduction

The archaeological study of human remains in modern conflict contexts is a subdiscipline of physical anthropology, which unites certain aspects of battlefield archaeology, disaster archaeology, and forensics (Cox 2005; Gould 2007; Scott et al. 2009). It centers on the recovery and analysis of human remains from armed struggles, such as battleground cemeteries, as well as remains associated with massacres, genocides, terrorist acts, prisoners of war (POW), those missing in action (MIA), and those held in internment camps.

Human remains associated with armed conflicts exist from all time periods and regions of the world (Martin et al. 2013). They are both a classical archaeological topic and one which overlaps extensively with modern forensics (Blau and Ubelaker 2011). Some of the oldest sites with human remains which fall under the umbrella of conflict remains include those excavated by traditional archaeologists such as Jebel Sahaba, Sudan (~13,000 years bp) and Nataruk, Kenya (~10,000 years bp). However, innumerable ancient and historic site types are studied within this discipline, be they the battlefield remains of standing armies such as those of the ancient Egyptians or Romans; the results of raids and localized warfare among peoples such as the Vikings or the inhabitants of Chaco Canyon, or the result of institutionalized aggression such as human sacrifice among the ancient Mesoamerican peoples (see Fiorato et al. 2007; Scott et al. 2009; Ralph 2013; Nielsen and Walker 2014).

Examples of more recent types of conflict remains include the search for the remains of the Romanov family after their deposition and murder by the Bolsheviks (1918); mass graves of citizens, prisoners, and combatants from multiple countries engaged in the World Wars; those associated with the Armenian (1915), Greek/Pontic (1914–1922), Indonesian (1965–1966), Assyrian/Seyfo (1914–1920), Serbian (1941–1945), Ukrainian/Holdomor (1932–1933), Bangladesh (1971), Cambodian/Khmer (1975–1979), Guatemalan/Mayan "Silent Holocaust" (1960–1996), Kurdish/Anfal (1986–1989), Rwandan (1994), Bosnian (1995), and ongoing Rohingya/Myanmar Genocides; groups of Mexican students kidnapped and murdered by modern drug cartels (2014); and those still missing in action from historic US military engagements (Ferllini 2007; Gould 2007; Scott et al. 2009; Gonzalez-Ruibal and Moshenka 2015; Naimark 2016).

Typical site types associated with the study of conflict remains include military cemeteries, battlefield graves, mass burial pits, isolated graves in combat zones, the sites of bombings and other large-scale acts of violence, and wreckages (Blau and Ubelaker 2011; Gonzalez-Ruibal and Moshenka 2015).

Definition

Conflict remains refer broadly to the internment sites, associated material evidence, and biological remains of human beings whose death was a result of internecine warfare or intergroup aggression (Blau and Ubelaker 2011; Dupras et al. 2011). In modern forensic archaeology contexts, these remains are particularly associated with prisoners of war and those missing in action. Violent conflict is often the result of a perceived difference between groups leading to beliefs of supremacy among the aggressor (Tropp 2012; Arendt 2014). Examples of such differences include religious belief, ethnicity, race, disability, political belief, biological sex, or social status (ibid. Martin et al. 2017).

However, violence resulting in the accumulation of conflict remains may also be derived from more practical or economic considerations (Martin et al. 2017). These include factors such as retribution for past aggression or oppression, competition for resources, access to and control of localities (such as religious or ancestral sites), the operation of criminal enterprises, and empire-building or glutting of surplus resources. A conflict may involve aggression by a powerful group against a powerless or pacifistic one. Alternately, the conflict may arise from and be perpetrated by multiple sides (Ferllini 2007; Tropp 2012; Arendt 2014; Naimark 2016). Violence may occur in dramatic, isolated episodes, or it may be more deeply ingrained within a quotidian social structure (Martin et al. 2017).

Conflict remains are unique in that they are typically studied using archaeological methods, forensic methods, or some combination of the two. They are also unusual in archaeology in that they range from very ancient to essentially modern (Blau and Ubelaker 2011; Dupras et al. 2011). The archaeological study of older conflict sites may be strictly academic, with typical archaeological aims and questions leading to research that informs the general history, culture, and lifeways of the relevant time period or event (e.g., Fiorato et al. 2007). In such research, standard archaeological method is also likely to be employed in the retrieval and study of conflict remains. Examples of more "archaeological" studies have focused on remains such as groups of shackled skeletons from Phaleron, Greece (eighth to fifth centuries BC); a mass grave of deposed royalty in the Mayan city of Cancuén (~800 AD); the Ridgeway Hill Viking burial pit in Dorset (970–1025 AD); mass graves of Aztec human sacrifices beneath Tenochtitlan (~1480 AD); burials from the Battle of Towton during the English War of the Roses (1461 AD); those from the Battle of Dunbar during the Third English Civil War (1650 AD); mass graves in Mexico City from the Aztec conquest by the Spanish (sixteenth century AD); or American Civil War Battlefields (1861–1865 AD) (Fiorato et al. 2007; Scott et al. 2009; Martin et al. 2017; Ralph 2013; Nielsen and Walker 2014).

In many instances, the study of conflict remains is a more forensic discipline, focusing on positive identification of individuals, as well as the causation and sequence of events leading to their demise (Cox 2005; Dupras et al. 2011; Christensen et al. 2014). This is often done with legal implications in mind, as the ultimate goal may be the repatriation of remains or the prosecution of war crimes (Ferllini 2007). Such excavations and analyses are conducted by forensic specialists with training in archaeological technique and physical anthropology (Dupras et al. 2011). Accordingly, although using similarly rigorous technique and documentation, such projects focus less on traditional archaeological cornerstones such as general patterns of human behavior and site formation. Instead, only the evidence which leads to the location of remains and the recognition of individuals may be prioritized (Cox 2005). This type of research and excavation may be undertaken by private contracting firms or specialist government agencies devoted to the purpose such as the United States Defense POW/MIA Accounting Agency. Typically, this type of archaeology is employed for US military personnel whose bodies have not been recovered, and the victims of terrorist acts or modern genocide, rather than for ancient sites (Gould 2007).

Historical Background

Since archaeology's inception, the archaeology of warfare and to some extent the human remains such conflicts generate have been a cornerstone of most cultural studies (Scott et al. 2009; Martin et al. 2013). War and the creation of empire was 1traditionally a popular academic theme surrounding the classical civilizations of the ancient Mesopotamians, Egyptians, Chinese, Greeks, and Romans (Carman 2013). This is due in part to the ability of archaeologists to draw on written accounts of battles from many of these cultures, such as Thermopylae and Qadesh (Ralph 2013). It is also due to a fascination with the world of the Greeks, Romans, and Egyptians among early archaeologists and the Victorian society from whence they came. At its beginnings, however, battlefield archaeology was more often a focus of historians rather than archaeologists. Human remains themselves often faded into the background, as battlefields were sometimes considered to have limited material culture (Carman 2013).

In more recent times, the archaeological study of violence, conflict, and warfare have found increasing commonalities between previously disparate subdisciplines and regions, as well as undergoing an ideological shift with increased focus on the study of human remains and considered violence from new perspectives (Martin et al. 2017; Carman 2013). Often, early studies of historic violence were part of a narrative of imperialism used to perpetuate stereotypes about savagery or primitivism in tribal cultures, whereas the large-scale military operations of empires such as the Romans, were viewed as an indicator of social sophistication (Arkush 2012). Even when encountering Meso- and South American civilizations, which were architecturally imposing and elaborate in their social strata, early archaeologists still often perceived their cultural manifestations of violence as indicators of barbarism. This is in spite of the fact that they were also elaborate, large scale, and socially complex (ibid. Nielsen and Walker 2014).

The emergence of modern physical anthropology has contributed to the current practice of conflict archaeology (Gonzalez-Ruibal and Moshenka 2015; Martin et al. 2017). The ability to study evidence of trauma to archaeological human remains has both revealed previously hidden examples of conflict, such as historical domestic violence, and supplemented formerly established narratives of large-scale conflicts with the ability contradict or confirm written sources (ibid.). This has accompanied a general shift in archaeological studies away from a selective focus on masculine activities and overarching social themes such as empire-building (Arkush 2012).

The hybridized study of conflict remains has also been bolstered by necessity: the forensic emphasis of more modern cases has leant and urgency to the discipline and increased funding which has helped to improve methodology at a faster rate than many other fields of archaeology (Cox 2005; Dupras et al. 2011; Christensen et al. 2014). Following conflicts, both ancient and modern, soldiers, governments, and families have sought to bring the remains of their loved ones home and get answers surrounding their deaths (Carman 2013; Martin et al. 2017). A notable ancient example of this type of conflict remains is the mummy of pharaoh Seqenenre Tao (~1550 BC), whose body is thought to have been were brought back to Egypt for traditional entombment, following death during battle with the Hyksos. This practice is in evidence throughout the archaeological record, often growing more urgent in instances of terrorism or genocide, in which one group is considered to be comprised of innocent bystanders (Ferllini 2007).

Following the Second World War, the American government began to devote resources to the retrieval of soldiers' remains on a large scale (Scott et al. 2009; Dupras et al. 2011). Although this was an ongoing process that began on the heels of the war, it was increasingly realized that simply exhuming remains was insufficient to lead to the positive identifications that would enable families to be reunited with the remains of their loved ones and gain closure. Although forensic experts had the tools and experience needed to identify evidence in crime

scenes, they were unaccustomed to the conditions specific to excavating what had essentially become historic burials (Cox 2005; Dupras et al. 2011; Christensen et al. 2014). Because of this, the discipline yielded a set of specialists with hybridized archaeo-forensic skills. With the advent of the terrorist bombings of September 11, and an increased national interest in forensics, the study of conflict remains became an independent profession in its own right from the last decades of the twenty-first century to the present (Gould 2007).

Key Issues/Current Debates

Because of the legal implications of forensic cases surrounding human remains from conflict contexts, many of the key issues in the field pertain to the development and refinement of methodologies for generating positive identification of individuals, and the study of skeletal indicators of traumatic injuries or pathology that can provide information about the individual's death and, if applicable, battle and/or captivity (Cox 2005; Dupras et al. 2011; Christensen et al. 2014). Despite the sometimes narrow focus of the identification of conflict remains, many of the methodologies furthered within the field have wide applications for all archaeological studies of human remains.

Since preliminary identification of individuals is paramount in forensic archaeology, studies of osteological evidence for identifying sex, ethnicity, and improved means of sourcing DNA from fragmentary or compromised remains are among the foremost concerns of the field (ibid.). Methods for observing and differentiating the metric and nonmetric traits that aid in these identifications are constantly being refined.

Improving the understanding of the interment sites and factors affecting retrieval is another focus pertinent to this goal (Cox 2005; Adams and Byrd 2014). These include taphonomic studies, such as those focusing on dispersal of remains in aircraft crashes; relative decomposition rates of remains in mass burial pits versus single interments; decomposition rates in different soil types and environments; and dispersal by fauna and other forces in instances where burial does not take place (ibid. Dupras et al. 2011; Christensen et al. 2014). Because many conflict burials include mass graves, studies focusing on the excavation techniques that preserve individual contexts and the identification of individuals from comingled contexts are another cornerstone of the discipline (Adams and Byrd 2014).

Because establishing the cause of death is desirable, studies of trauma indicators to osseous remains are another central preoccupation (Cox 2005; Dupras et al. 2011; Christensen et al. 2014). This is true of both more classical battlefield archaeology, as well as forensic contexts. Osteological evidence of blunt force, sharp force, gunshot, and loading trauma may be observed during conflict for a variety of reasons (Cox 2005; Dupras et al. 2011; Christensen et al. 2014). Differentiating between defensive injuries can help to establish whether the victim of violence was able to fight back, and if so, to what extent. In the case of more historic remains, the study of injuries resulting from melee and ranged weapons such as arrows is more common. However, in modern forensic cases, gunshot trauma increases alongside other forms of weaponry still in use. Although most ancient remains will be only osseous, soft tissue may be present in the case of human remains from historic conflicts, opening new avenues into studies of soft-tissue trauma and pathologies. The burning of remains is another taphonomic/traumatic marker which receives study in the field, as remains may be burnt during bombing, plane crashes, or intentionally after death to obscure evidence (Schmidt and Symes 2008). The study of modern conflict remains also includes the osteological study of the relatively unique trauma that is associated with explosions and other high-force impacts (Cox 2005; Dupras et al. 2011; Christensen et al. 2014).

Finally, the veracity of records is an issue which arises in both classical conflict archaeology, as well as in archaeo-forensic cases (Scott et al. 2009). In ancient military situations,

records may misrepresent an event, to make a defeat appear less crushing. Sometimes, a group suffering more losses may even falsely portray themselves as the victor. In modern forensic cases, the truth may be purposefully obscured, particularly where crimes have been committed on a large scale (Ferllini 2007). As such, a common goal of both classical and forensic archaeology involving human remains will always be to arrive at the most objective picture of the events leading to their deposition. As with all cases where human remains are concerned, the careful and respectful treatment of the remains and the associated data is necessary to mitigate the numerous ethical issues which may arise from their disturbance and study.

International Perspectives

As conflict continues in the modern world, there are few modern cultures who are not affected on some level by ongoing instances of violence. Americans are well known for their dedication to retrieving all the remains of their war dead, whereas other western cultures typically do not pursue this archaeo-forensic goal (Gould 2007). Despite this, cultures which deal with instances of genocide or terrorism generally conduct forensic recoveries on the remains, in instances when the aggression has abated to the extent that doing so becomes feasible (Ferllini 2007). In recent years, this has been common in certain eastern European; meso- and South American; and Middle Eastern countries (Martin et al. 2017). Although professionals in these settings may employ aspects of the archaeological method, their focus may be even more forensic, depending on the resources and training available to them.

Future Directions

Many large-scale recovery operations surrounding the retrieval of war dead and the victims of genocide are considered to be ongoing until a point is reached where further recovery becomes infeasible (Gould 2007). As future incidents associated with war, mass murder, and terrorism occur, new recovery efforts will continue to be necessary.

Human remains associated with traditional warfare contexts continue to be a popular area of study within classical archaeology in most regions of the world (Carman 2013). Increasingly, historical narratives surrounding violence are being reinterpreted from local and minority perspectives, whereas many themes had historically focused on western or majority imperialism, nationalism, and conquest (Arkush 2012). Future studies will likely arrive at different interpretations surrounding more recent instances of violent behaviors (Martin et al. 2017). As various groups continue to interpret the violence in their past, they may include the human remains from more recent conflicts in their archeo-forensic studies, including their POWs and MIA individuals. There is still much to be learned in terms of narratives of historical events in warfare, when conflict remains are considered in a larger archaeological framework.

The retrieval of human remains from recent conflicts becomes more difficult as time passes, necessitating an increasing archaeological focus and improved forensic methods (Cox 2005). In addition to attrition through natural forces, more recent battlefield archaeology is an arena which attracts hobbyist metal-detectors and collectors of memorabilia. In many cases, sites are located through the cooperation of aging primary witnesses. As such, public outreach and ethnographic record keeping of salvage events are an essential component of resolving future and ongoing cases.

Human Remains in Museums

Cressida Fforde
National Centre for Indigenous Studies, The Australian National University, Canberra, ACT, Australia

Introduction

Human remains have long been acquired for study and display in public and private museums and those of universities and learned societies worldwide. They are today to be found in a range of collections, but particularly those associated with anatomy and the medical sciences, archaeology, anthropology, ethnography, and natural history. They have also, historically, been located in phrenology museums and were subject to acquisition as curios whether within small private collections or the larger cabinets of curiosity compiled by prominent individuals and monarchs of renaissance Europe. The contents of some of these curiosity cabinets are now to be found in museums today, and indeed sometimes formed the basis of their initial collections.

Definition

All types of human remains have been acquired by museums, including ancient and modern skeletal and soft tissue as well as remains crafted into (or incorporated within) objects. Some museums contain many different types of human remains, but, in general, the type of remain acquired depended upon the disciplinary interest and/or research focus of the collector or collecting institution. Thus, to provide a few examples, human remains of normal or pathological structure are generally found in the collections of anatomy, pathology, and the medical sciences; archaeologically excavated human remains are usually to be found in archaeology units or relevant university departments; and remains from non-European cultures that have been in some way changed by

the action of humans are often to be found in ethnography museums. Of course, in the larger regional or national museums, different types of human remains may have been obtained by different departments within a single institution.

Over the history of scientific interest in human remains, relevant disciplines have emerged and become redundant or are now taught in different ways and have a different research focus, and these changes have had consequences for the future and location of associated collections. Thus, for example, in the early nineteenth century, phrenological societies acquired crania and cranial casts in order to demonstrate that examination of head shape could determine individual and so-called racial character (MacKenzie 1820; De Guistino 1975). But as phrenology increasingly lost credibility and entered the realm of pseudoscience, the contents of some of these museums were absorbed into the expanding comparative anatomy (later termed physical anthropology) collections of the mid-nineteenth century. Thus, for example, the large collection of the Edinburgh Phrenological Society was transferred to Edinburgh University's Anatomy Department during this period. The skulls collected by phrenologists then became the focus of race-based science which sought to describe and understand "racial" diversity and origins, a central research interest for many anatomy departments at that time. These "race" collections were in the majority composed of crania (because it was thought that the skull most clearly exhibited racial characteristics) and commonly formed significant components of large and imposing anatomy museums that were architecturally and pedagogically central to medical schools during this period (Alberti 2011a).

"Race" collections account for a large number of curated human remains, and were compiled between the late eighteenth and early twentieth centuries to represent the diversity of humankind. In the United Kingdom, the majority of remains in these types of collections are European in origin but a large component was taken from geographical locations worldwide. Museums wishing only to display representative so-called racial types only acquired small numbers of crania, but those with a strong research agenda in this area compiled extensive collections for measurement and analysis that could number in the multiple thousands. At that time, the scientific significance of a collection was dependent upon its size and geographical diversity.

Remains were obtained from all the different places that the dead can be found. While the majority were taken from burial grounds, either through excavation or chance recovery, remains were also acquired before burial, such as from sites of violent death, and prison or hospital morgues. There is a small but significant number of individuals who were killed or executed for their part in resistance to colonial expansion and their skulls or preserved heads sent back to the UK (Turnbull 2002; Fforde 2004). Institutions in Europe used extensive collecting networks to obtain remains from around the globe. Thus, for example, universities were sent remains by past students, army medical museums relied on medical officers serving abroad, and learned societies utilized their international membership. Private collectors relied more heavily on purchase as well as expending considerable effort creating relationships with potential collectors "in the field." Associated documentation (e.g., donor correspondence and museum catalogs) can provide some indications of the historical responses of those whose dead were removed. Whether couched in terms of collectors having to be clandestine in the removal of remains, descriptions of unease and fear shown by local people at the disturbance of graves, overt warnings and threats to collectors, requests for remains to be returned, or outright opposition, the historical record contains ample evidence of local concern and resistance.

The nineteenth and early twentieth century research undertaken on these remains was deeply embedded in the race paradigm and consequently deeply racist in nature. Such research reified incorrect and preconceived notions of racial hierarchy that had been present for centuries. The so-called Order of Mankind, ranked different "races" on an hierarchical ladder which normally placed the European male at the top and others in descending order below, with typically Australian Aboriginal people or Tierra del Fuegians at the

bottom. After the introduction of Darwin's evolutionary theory, human remains were increasingly investigated for "evidence" of the evolutionary "stages" through which Europeans had passed (Haller 1971). Thus, for example, work was undertaken on skeletal remains to investigate the "lowly" physical characteristics of Aboriginal people (e.g., Duckworth 1908; Berry and Robertson 1911) and to identify physical and cultural "evidence" in the "lower" races to show that they were the modern representatives of past European populations (Sollas 1911). The legacy of this type of research, and the influence it had on the development of deeply oppressive legislation which impacted on colonized people, was to become a significant element in the concerted calls by various Indigenous peoples for the return of their ancestral remains which began in earnest in the 1980s (see below).

By the mid-twentieth century (and particularly in response to the atrocities of Nazi Germany), the scientific profession increasingly abandoned race as a valid biological concept (Reynolds and Liberman 1996) and moved on to different research questions that needed well-provenanced remains excavated with archaeological techniques. This combination of criteria was rarely found in the old "race" collections which became largely redundant during this period, as did the large pathology collections and those illustrating normal anatomy. This lack of use, coupled with the development of new teaching techniques and acute pressure for space, saw many anatomy museums dismantled. Their contents were either transferred to other museums or placed in store where they remained largely forgotten until indigenous interest in reclaiming the bones of their ancestors drove significant research into locating and provenancing collections in the 1990s.

The complex history of acquisition and transfer of collections is well illustrated by that of the Royal College of Surgeons of England. The College's new buildings in Lincoln's Inn Fields, London, were opened in 1813 and incorporated a central museum, the nucleus of which was formed by the anatomical collection of distinguished surgeon John Hunter (1728–1793), which had been purchased by the British Government in 1799. Published and unpublished catalogues of the collection chart rapid growth during the nineteenth century. Significant components included a substantial series of human remains from around the world (its "Human Osteology" series) as well as a large number and variety of pathological and anatomical preparations of humans and animals. The College relied largely upon the work of individuals collecting overseas, as well as obtaining remains acquired by scientific expeditions, by purchase from auction houses in London, and through international trade and exchange programs with other museums, such as The Auckland War Memorial Museum in New Zealand (Fforde and Hubert 2006; Tapsell 2005). It also purchased two significant "race" collections: that of the Anthropological Society in 1890 (approximately 300 skulls), and that of private collector Joseph Barnard Davis in 1867 (approximately 1,540 skulls). The College collection is typical in its composition. The majority of the remains in the osteological series were from Europe but a large proportion were from other countries, and most were represented by crania, although the museum also acquired a much smaller number of full and part skeletons as well as some soft tissue remains. By the time its 1907 catalogue had been published, the College probably contained the largest "race" collection in Britain, and perhaps in Europe (Flower 1907).

Interest in studying the collection declined in the first half of the twentieth century, and in 1941, the Museum received a direct hit in a bombing raid of London. Although a significant portion of the museum was destroyed, over 6,300 items in the "race" collection survived, with a subsequent report indicating that damage was geographically selective (Cave 1941: 8). After the war, the surviving "race" collection, with the exception of those remains that had once been part of John Hunter's museum, was transferred in stages between at least 1947 and 1955 to the Natural History Museum in London. The College's Hunterian Museum continues to curate human remains obtained for anatomical, pathological, and medical research over the past century.

Key Issues

Over the past 30 years, there has been increasing attention paid to the ethics of human remains in museums. The "race" collections of old have been the subject of intense debate, driven by the campaigning of various Indigenous groups (particularly in Australia, North America, South America, Scandinavia, and New Zealand) for the return of their ancestral remains removed so many years ago. Their requests, which articulate strongly held spiritual beliefs and obligations as well as deep concern about the theft and misuse of their ancestors' remains, were initially denied by almost all holding institutions which argued instead for continued retention based on scientific importance. The resulting debate was high profile and often contentious and became known as the "reburial" or "repatriation" issue (Layton 1989; Fforde et al. 2002). In some countries, it has driven change in museum and professional practice and policy and slow but increasingly successful rates of returns to Indigenous groups worldwide (Hubert 1989; Watkins et al. 1995; Watkins 2003; Fforde 2004; Hole 2007; Hemming and Wilson 2010). Campaigning by Indigenous groups and their supporters has meant that many in the archaeology, museum, and anthropology disciplines have closely scrutinized the history and practice of their professions and developed new policy in relation to contested human remains and cultural heritage (Phillips and Allen 2010). There has also been intense discussion about the ethics of display of Indigenous human remains and of human remains in general (Swain 2002; Alberti et al. 2009; Sayer 2010: 95–109).

The question of ethics has also arisen in relation to anatomy and pathology collections of less than a hundred years old, of which the work of the Human Tissue Authority (HTA) in the UK is an example. However, with the decline of the great anatomy museums of the nineteenth and early twentieth century, a perhaps more prominent issue has been the future of the large number of anatomical and pathological specimens that they once housed. No longer in high demand for teaching use, such items take up space and, if wet specimens, are costly to maintain. For these reasons, many pathology collections were destroyed in the late twentieth century, although some have been retained for teaching purposes and to illustrate medical history. Emerging research in the development and history of medical museums provides important context and information about the potential future of the human remains they contain (e.g., Reinarz 2005; Alberti 2011a, b).

Human Remains Recovery: Archaeological and Forensic Perspectives

John R. Hunter
MFL Forensics, Wantage, Oxfordshire, UK

Introduction and Definition

Forensic archaeology involves the application of archaeological theory to scenes of crime, usually in the search for, and recovery of, buried human remains and associated evidence (Hunter and Cox 2005; Blau and Ubelaker 2009). This transfer from more conventional archaeology is not straightforward: there are a number of operational, legal, and procedural divergences from the parent which makes forensic archaeology a discipline in its own right. All archaeology involves the study of the shallow substrates; it bases its methodology on the principles of stratigraphy which are empirical. By nature, archaeology is an invasive and destructive process.

Stratigraphy is the result of formation processes by which surface deposits will accumulate, often unperceivably, over time in a given place. These deposits can reflect both human (cultural) or natural changes. Examples of cultural changes can include layers resulting from construction, fire, occupation, digging and filling pits, demolition, agriculture, and so on; examples of natural changes can include silting, movement of soil downhill, geological movement, erosion, or peat and soil formations. All these, individually or in

combination, can result in the development of layers of various thicknesses, characters, and properties. Interpreting what activities these layers reflect and the order in which they were created is the basis of archaeological study. Interpreting what the layers signify allows us to create a statement of what went on in a given place; examining the sequence of those layers provides us with a time line of their relative formation (Fig. 1). They all occur in past time, and it makes no difference to their study whether that was 10,000 years ago or yesterday morning – the same principles of investigation apply.

If a grave is dug into the ground, it creates an additional layer (i.e., the grave) in the statement of what went on in that place, and it adds a new point in the time line. In other words, the grave has a context in time and space. The grave also has boundaries – the grave walls, base and top of the grave fill. It needs to be viewed three-dimensionally as a sealed unit (rather like a coffin) inside which is contained the individual victim, material associated with the victim (clothes, jewellery, contents of pockets, etc.), and any evidence which may link the offender to the digging and infilling of the grave itself (e.g., hair, fibers, or anything deposited in the grave for concealment purposes). In many respects, the grave should be viewed as a mini crime scene. It makes no difference whether this is a single victim grave or a mass grave containing large numbers of victims. However, once human remains become removed from this burial context, all these associated evidences are, at best, minimized in value and at worse, lost completely. The burial context (the totality of the grave) is not only key to the integrity of the body and its associated materials but also fundamental to the veracity of evidence presented in court.

Unfortunately, most buried human remains are discovered accidentally during construction work, drainage, or even gardening, often being pulled out of the ground by the finder or the police. Instructions to police forces are to leave them where they are and *not* to remove them. This allows an archaeologist to evaluate the context of the grave in relation to surrounding layers. Sometimes this can be simple, for example, when a skeleton is located under a house foundation of known date, or more difficult when there are no clearly defined or identifiable layers surrounding the burial on which to base a context or relative date. Sometimes human bones are found scattered on the surface with no context at all. In such cases, it needs to be ascertained whether they were originally buried (i.e., with a context) and

Human Remains Recovery: Archaeological and Forensic Perspectives, Fig. 1 The photograph shows the formation of buried layers representing sequences of events

have been brought to the surface by scavengers or whether they belong to a surface deposition. This involves a wider landscape analysis in order to identify disturbances or other remains respectively. Formation processes occur all the time and are just as relevant to modern as to historical graves. Sometimes local events (e.g., ditch clearance, gravel spread, or reseeding) can have recorded (or remembered) dates that will give the grave a *terminus ante quem* (time before which); often perpetrators may attempt to disguise graves with paving or similar surfaces or by "importing" soils from elsewhere. All these activities leave discernible traces in or on the ground.

Key Issues

Locating Buried Human Remains

Locating remains below the ground surface is one of the cornerstones of archaeological practice. Over the years, archaeologists have adapted, developed, and honed various techniques in order to achieve this. The majority of methods are non-invasive (often referred to as "remote sensing") and have advantages and limitations according to environment, landscape, and operational conditions. Different techniques and strategies can be adapted according to merit depending on the character of location – these can vary from a small back garden to open moorland; they also depend on the questions being asked in a particular enquiry. It is sometimes forgotten that the application of these techniques in the discovery of buried human remains can differ from the same techniques used in the discovery of conventional archaeological remains such as buried walls, ditches, and pits. This difference is brought about by the decay dynamic of the buried human body. This decay process is well documented, but the speed at which it occurs varies according to, *inter alia*, the buried environment, climate, wrapping/clothing, and other factors, and as such the decomposition stages at which the effects of certain techniques may be optimized or minimized (e.g., liquidification, heat emission, skeletalization) may vary enormously (Boddington et al. 1987; Vass et al. 2002).

The main techniques used in landscape search and analysis are well documented and only need outlining here (Killam 1990; France et al. 1997; Ruffell and McKinley 2008; Cowley 2011). Aerial methods include photography, satellite imagery, and Lidar (see below). All have their advantages and limitations, but all of them (with the exception of thermal imaging) will be detecting not the buried body per se, but the disturbance made in burying it (i.e., the grave). When a grave is dug and filled in again, it can present a different base for surface vegetation simply because the fill of the grave tends to be looser, more aerated, and contains a mixture of all the soils lying adjacent in undisturbed ground. As a result, the surface vegetation may differ from the surrounding flora: Its growth may be enhanced or stunted, and it may attract different species or follow a differing flowering regime. The disturbance itself may have drawn distinctive subsoils to the surface such as chalk or colored clays.

Aerial imagery uses light (shadow), crop variation, and soil marks to locate disturbances; it may pick out topographical expressions caused by slight mounding on the ground surface or a sinking of the ground when the infilled soils of the grave begin to consolidate. Detecting these features depends on angle of light, season, and crop regime. If the conditions are not appropriate, the evidence of disturbance might be missed. On the positive side, this kind of evidence can be long term, which is why archaeological remains hundreds of years old can still be detected from the air providing the conditions are favorable.

Larger targets, particularly those of significant vegetation change such as mass graves, might also be detected by satellite imagery, depending on pixel resolution, using the same principles. Many mass graves, notably those in the former Yugoslavia from the 1990s, are approximately 3 m wide (roughly the bucket width of the mechanical excavator used in their construction), typically some 10–20 m in length, and are of appropriate size for vegetation change to be detected by satellite. Lidar is a relatively new asset and involves producing a digital terrain model (DTM) by firing multiple radar pulses from an aircraft in flight. Depending on the

number of points per meter reflecting from the ground, this may be able to identify subtle topographic change on the ground surface and can even penetrate tree canopies. The application is novel but has potential.

On the ground, geophysical survey has a role to play in targeting; it has the ability to detect shallow anomalies below the ground surface. It will not define what those anomalies represent, and it requires a relatively "quiet" and consistent geological background in the immediate surrounding area in order for the anomaly to be observable. The techniques used tend to be electrical (e.g., resistivity), magnetic (e.g., magnetometry), or electromagnetic (e.g., radar); they all respond to different characteristics of the substrates and are not substitutes for each other. Like other techniques, they all have advantages and limitations depending on environment and context. Ground penetrating radar (GPR) has become a popular choice for the simple reason that it has the ability to penetrate solid surfaces (e.g., patios, driveways, swimming pools) and can deliver data in "real time" (i.e., during the survey itself). All search methods share two common features: None of them are infallible, and the output is only as good as the person who interprets it.

Search assets are best used in combination and in a defined sequence. Search is as much about elimination as about discovery, and the cadaver dog can have a powerful role to play in this process. The cadaver dog, for example, can find a useful role in being directed to anomalies detected by GPR as a secondary source of validation. Targets will require venting (i.e., probing the ground to facilitate release of any gasses), and if the dog responds, the anomaly can be excavated or investigated further. A negative dog response can normally allow the anomaly to be eliminated. Neither GPR nor dog (or any other search asset for that matter) can be used with 100% confidence, but if they are used in combination, the probable likelihood of error is reduced to an acceptable level. Cadaver dogs can be used in a similar way to investigate freshly turned soils in a suspected garden or potential targets identified from aerial imagery. Although dog work requires venting probes to enter the ground, the technique is only mildly invasive. The use of complementary or sequential assets such as this is a realistic and practical operational procedure.

More invasive but more effective for larger areas of search is the technique of mechanical stripping. The use of heavy machinery to investigate a site can be very useful in cases where an allegation has been made of a burial located within an area that can only be generally defined or where an area needs to be eliminated with 100% confidence. The process requires the upper surface of the ground to be stripped off horizontally using a wide toothless ditching bucket, working on the principle that the disturbance caused by the grave digging will be visible within otherwise disturbed natural soils below (Fig. 2). Normally this can be achieved, and land eliminated, at a depth of around 0.3 m depending on conditions, but the process is invasive and has the potential to strip off some of the grave fill evidence as well. It is a compromise between, on the one hand, the need for speed and the efficient use of resources and, on the other hand, the necessity of discovering the body/ies. That said, mechanical stripping is a very effective tool and can be manipulated sensitively by an experienced operator.

Searching for human remains is a special exercise: in addition to assessing information provided by witnesses, it can involve the analysis of landscape, topography, and the definition of features on a landscape. The starting point for this is the map in its many forms. Maps provide basic landscape data, but other data sources such as surface geology and land use (which can inform feasibility of burial) also need to be incorporated if target areas are to be defined. The use of geographical information systems (GIS) has a major contribution to offer here in allowing the landscape to be converted into a DTM over which different layers of information can be draped (e.g., Orengo 2008). Not only can it incorporate layers such as geology and land use but it can also be used to generate view sheds and hence zones of the landscape which offer concealment from roadways or nearby houses. As a result of this, GIS can also be used to target particular landscape zones or to prioritize one zone over another on the basis of practical factors. Moreover, the results from

Human Remains Recovery: Archaeological and Forensic Perspectives, Fig. 2 Machine stripping of a suspect area to detect disturbances brought about by a clandestine burial

geophysics, line search, and dog deployment, etc., can also be added to the model to show, for example, areas covered and the degree of search thoroughness. GIS data can be repeatedly interrogated, or items added or deleted.

Excavating Clandestine Graves

Identification of the grave allows an archaeological strategy for recovery to be designed. All clandestine depositions are different and, although there is no "by-the-book" methodology, every recovery process will recognize common stratigraphic principles, the destructive nature of the process, and, as a result, the importance of making adequate records (Hanson 2004; Cheetham and Hanson 2009; Hunter 2009). An offender digging a grave will undertake three processes, usually in quick succession: the digging of a hole (the grave) and the depositing of spoil on the adjacent ground surface, the deposition of the victim in the grave, and the backfilling of the grave. The archaeologist will address the grave in reverse order, first by emptying (excavating) the grave and recovering evidence within the grave and the fill, then removing the body, and then recording the grave itself. In order to understand *how* the offender filled in the grave, it is often standard practice to excavate a half-section first: this involves excavating the grave from one half of the grave only; it allows the creation of a profile through the grave and shows, for example, tip lines, the presence of additional layers introduced to the grave fill, or any attempted concealment layers introduced by the offender. Sections provide a vertical view of the formation process which cannot be obtained in any other way.

Most grave fills are a mixture of the layers through which the grave has been dug. Excavation normally involves removing one layer at a time and recording each one individually by unique numbering and with a detailed description of its color, characteristics, and mineral inclusions. In a mixed grave fill, this is normally carried out by defining arbitrary layers as "spits," typically 10 cm deep, but recording each in the same way as a "real" layer. Objects which are recovered from the excavation can be associated with the layer or "spit" from which it derived. This allows a coarse reconstruction of where they were deposited in the grave fill. A more sophisticated method of recording can be achieved by electronic means, by deploying a total station electronic distance measurer (EDM) which can record points accurately and allow the shape of the grave and any associated objects to be reconstructed in three dimensions. It offers immense advantages but is

Human Remains Recovery: Archaeological and Forensic Perspectives, Fig. 3 The sides of the grave need to be followed carefully in order to avoid contamination and to record implement markings

not always viable in crime scene conditions located within enclosed spaces or where there are sight-line obstacles such as trees or buildings.

The edges of the grave need to be followed carefully using small hand implements (Fig. 3). This is not simply to ensure that the fill of the grave is not contaminated but also to preserve any implement marks. Often, especially in plastic soils such as clays, there may be impressions or tool marks surviving in the grave walls, or even footprints impressed into the grave floor. In some excavations of mass graves, the approach taken is to excavate a trench all around the grave giving a pedestal effect in order to facilitate access (Cox et al. 2007). This has its advantages, but it also has the effect of destroying marks in the grave wall. In deeper or larger graves, one solution is to dig a small platform to one side of the grave once the excavation has reached a depth of about 30 cm and the exposed part of the grave wall has been recorded, then continuing the process in stages until the excavation is complete. This allows any impressions in the grave wall to be recorded fully and also facilitates operational access to the grave itself.

Because excavation is a destructive process, it often requires specific forensic questions to be asked. These vary according to circumstance but can typically relate to the manner of grave creation and the implements used, whether the grave was dug in a hurry or carefully prepared, if there were any objects or trace evidence within the grave fill, or if the grave contained any foreign material that might lead the enquiry to a different location. There are also questions relating to the identity of the victim and the manner/cause of death, not to mention the overriding question as to who killed the victim. The answer to the last question may not be readily apparent from excavating the grave, but the evidence contained within the grave may provide new information that will contribute to an answer.

Archaeology is an interrogative exercise: The range of questions that need to be asked in a particular enquiry will inevitably influence the methodology. Finding the body is only a part of the process; being able to answer key questions such as these is why experienced archaeological input is so essential. Once a body has been lifted from a grave, the evidence has been largely destroyed and the opportunity lost. The need for formal recording systems is therefore paramount. This is not just a matter of written records per layer but also of detailed photography and of plans drawn to scale. These constitute the primary field record of work carried out and underpin both the archaeologist's account and the evidence given in court.

Soils and other material removed from the grave may need further investigation according

to questions being posed by the enquiry and according to potential survival (e.g., Janaway 2008). Sieving, for example, may be used for the collection of any small items (including bones) that may have been missed at the scene. Sieving according to layer or "spit" will ensure that any such items can be identified with a particular part of the grave. Depending on the state of the soils, sieving can be undertaken dry (i.e., by riddling through a mesh) or wet, whereby a jet of water is used to break down thick soils or clays through a grid. Mesh sizes vary according to what is been searched for: A 5–10-mm mesh will capture most larger objects, but smaller mesh sizes will be needed for tiny articles such as very small bones. The recovery of trace materials (e.g., human hair and fibers from the perpetrator which may have entered the grave fill) will require a more subtle approach, controlled laboratory conditions, and sieving down to levels of microns. Both hair and fibers are known to survive for variable lengths of time in buried environments, according to conditions.

The report of the excavation will incorporate all these evidence types measured against the methodology employed and the answers to specific questions asked. It will be open to cross-examination, and the archaeologist will be required to support his or her findings and interpretations on the basis of the records made. Once a grave has been excavated, there is no going back to do it again.

Human Remains: Ethical Issues and Historical Perspectives

Jayne-Leigh Thomas
Indiana University, Bloomington, IN, USA

Introduction

Over the last few decades, there has been an increased acceptance of rights over cultural heritage within the field of archaeology, as alternative views are incorporated into research design and researchers relinquish sole custody of the archaeological record. However, this inclusion has brought about the intersection between vastly different opinions regarding the ethical treatment of the dead. What constitutes appropriate treatment of human remains varies from culture to culture, and the sensitivities surrounding their treatment often create ethical dilemmas and conflicts between stakeholders, which are less commonly found in other areas of archaeological study.

Definition

Ethics can be defined as a system of moral values that specify a particular code of conduct, often defining "right" and "wrong" (Goldstein and Kintigh 1990: 585; Mays 2010: 331, 347). However, as Goldstein and Kintigh state, ethical principles are "culturally constructed" and will vastly differ depending on the cultural group defining such principles (1990: 586; Sellevold 2010: 141).

Historical Background

The practice of collecting human remains for scientific pursuits can trace its roots back to the third century B.C. in Ancient Greece, where the bodies of condemned criminals were obtained for systematic dissections for anatomical knowledge (Walker 2008: 5; Von Staden 1992: 223). Such activities were discouraged in the following centuries due to religious beliefs regarding the body and the afterlife; however, during the Renaissance, the prevalence of anatomical studies began to increase as the cadaver's medical value was recognized (Walker 2008: 5; Lambert 2012: 18). The creation of "curio cabinets" containing human remains became a popular hobby among the wealthy, specifically those interested in anatomy and scientific examination (Walker 2008: 10). The need for "specimens" soon led to grave robbing, of primarily underprivileged and disadvantaged individuals, throughout the United States, Britain, and many other countries.

During the 1700s, scientific studies began to focus on human diversity and population differences, which led to the large scale collection of skeletal remains. Specifically, crania were sought for phrenology and racial classification studies, which focused on the idea of an evolutionary hierarchy and that racial intellect was dependent on cranial capacity and measurement (Dickerson and Ceeney 2014: 90; Walker 2008: 8; Lambert 2012: 19). Throughout the nineteenth and early twentieth centuries, vast collections of skeletal remains were stolen and collected from battlefields, cemeteries, and archaeological excavations as large, newly founded museums sought to augment their collections and to continue research on human remains (Walker 2008: 6). Throughout Europe, as archaeology became an established discipline, new interpretations based on racial segregation further exacerbated views of cultural

division such as "primitive" versus "civilized" (Holand and Somerseth 2010: 25).

During the last few decades, archaeologists have moved away from craniometry and studies on human variation to focusing on the way environmental and cultural conditions factor into human development (Martin et al. 2013: 31). Such topics include nutrition, disease, trauma, and violence (Martin et al. 2013: 31). New methodologies such as DNA and stable isotope analyses have allowed for in-depth studies on human adaptation and population health; however, until recently, the majority of these research studies on indigenous human remains have failed to incorporate and recognize external perspectives from native stakeholders, creating contention and conflict with local communities.

Key Issues/Current Debates

A large portion of archaeological collections containing human remains in museums across the globe are a product of colonial pursuits, racist ideology, and Western imperialism. Similarly, research to date has primarily focused on Western views rather than incorporating community-based, participatory research. Disagreements on the treatment of human remains have arisen between researchers and Indigenous communities as their culturally constructed sets of ethics conflict (Goldstein and Kintigh 1990: 586; Larsen and Walker 2005: 118; Scarre 2013: 673).

Traditionally, human remains have been viewed by the scientific community as objects of research with potential for understanding the overall history of the human species (Larsen and Walker 2005: 111, 113; Walker 2008: 13). They are considered to be a vital resource of mortuary information, and those working with skeletal remains often consider it their ethical responsibility to obtain as much data as possible from those remains in order to contribute to the overall archaeological record (Klesert and Powell 1993: 350; Sellevold 2010: 141).

In contrast, many Indigenous communities view continued excavation, retention, and study of human remains as disrespectful and highly offensive (Henderson 2009: 55). The dichotomy is further exacerbated by the overwhelming emphasis on research by Western science as opposed to the incorporation of native participation or ideas. Many native scholars have been highly critical of archaeologists, viewing their work as self-serving, racist, exclusionary, and lacking any real meaning to contemporary populations (Henderson 2009: 55; Walker 2008: 13; Zuckerman et al. 2014: 515). For many, the return of ancestral remains recognizes the wrongs suffered during colonialism and promotes the healing of native communities (Henderson 2009: 57; Mays 2010: 332).

Walker (2008) outlines three ethical principles which should be utilized when working with human remains: (1) human remains should be treated with dignity and respect, (2) descendants should have the authority to control the disposition of the remains of their relatives, and (3) owing to the importance for understanding the history of our species, the preservation of archaeological collections of human remains is an ethical imperative. While these principles can be applied to the overall treatment of human remains from any collection or country and are primarily from a bioarchaeologist's viewpoint, Walker recognizes there are intrinsic problems with such ethics, for example, when the preservation ethic conflicts with relinquishing control to the descendants (2008: 20). Additionally, the term "respect" is culturally defined and varies globally. Some archaeologists may maintain that they are being respectful of the dead, but that definition of respect is often not the same as that of the descendants of the remains.

There may also be situations where there is no surviving population of descendants who can provide a voice for the deceased or where political circumstances have silenced their voice. Zuckerman et al. (2014) propose the concept of relational ethics for working with the deceased, specifically those from disadvantaged or oppressed populations. This follows an idea of "ethics of social responsibility" where the human remains are not considered as specimens of information, but active participants in their storytelling and where the researcher acknowledges the

descendants' connection with the deceased (517). Additionally, such an approach would maintain that agency and value be attributed back to the remains and stories of oppression and power could be told, giving a voice to those who were silenced and who would otherwise be obscured from record, such as in forensic cases or in situations of genocide or war (517–518).

International Ethics and the Repatriation Movement

The strong response to the curation and study of human remains has been the cry for repatriation and reburial by indigenous parties, largely in countries such as the United States, Australia, and Canada, where European colonialism displaced and marginalized native communities and illicitly appropriated indigenous human remains (Bienkowski and Coleman 2013: 83; Henderson 2009: 56; Mays 2010: 333; Lambert 2012: 25). While often considered a more recent movement within archaeology, discussions of the ethical treatment of human remains began as early as the 1960s (see "▶ Repatriation Acts: Before NAGPRA"). The establishment of the American Indian Movement and intense activism by Native Americans in both the United States and Canada brought a focus on scientific colonialism, and tribal groups began lobbying for the return of their ancestors and cultural items in an effort to regain control over their cultural history (Ferguson 1996: 68; Zimmerman 2012: 99). In 1976, the first state reburial law was passed in Iowa in response to the unequal treatment of an inadvertent discovery in 1971 where Euroamerican remains discovered were reburied without study and the Native American skeletons were sent to the local museum for research purposes (Zimmerman 2005: 61; 2014: 2).

Throughout the 1980s, issues regarding reburial began to be globally discussed and the ethics of studying human remains became under scrutiny (Webb 1987: 296). Numerous archaeologists began recognizing indigenous communities' right to control their heritage and arguing for the incorporation of community-based research with the goal of collaborative assessment and mutual understanding (Pardoe 1990: 208). Indigenous considerations needed to be placed at the same level as scientific enquiry and for this to be done, archaeologists needed to concede not only ownership of the remains but embrace multiple perspectives of the archaeological record (Pardoe 1990: 222).

In 1986, the first meeting of the World Archaeological Congress (WAC) was held in Southampton, England. One major point at this international conference was the inclusion of indigenous and Third World peoples – without their representation, archaeology would fail to be considered truly world-wide (Zimmerman 1994: 5). Three years later, a special topic WAC Inter-congress was held in Vermillion, South Dakota, titled "Archaeological Ethics and the Treatment of the Dead." During this conference, the Vermillion Accord on Human Remains was adopted, outlining six principles of respect for both indigenous and scientific viewpoints (http://worldarch.org/code-of-ethics/). In 1990, WAC passed the First Code of Ethics in Barquesimeto, Venezuela, recognizing the importance of considering indigenous communities as equal research partners and recognizing their interest in preserving and investigating their own heritage (Zimmerman 2005: 64).

After several decades of lobbying by Native American communities, advocacy by numerous archaeologists, and the enactment of nearly 40 state repatriation laws, the United States Congress passed the National Museum of the American Indian Act in 1989 and the Native American Graves Protection and Repatriation Act (NAGPRA) in 1990. Addressing only the collections housed within the Smithsonian, the NMAI Act was designed to set forth procedures for repatriation of Native American human remains and cultural items. For all other institutions receiving federal funding, NAGPRA created a similar mechanism whereby Native American tribes and Native Hawaiian organizations may claim and receive ancestral remains, funerary objects, sacred objects, and items of cultural patrimony through repatriation. It is an important piece of human rights legislation which addresses the institutional treatment of Native American remains and the lack of

consideration for their beliefs (DeWitte 2015: 12). NAGPRA covers three main topics: (1) the inadvertent discovery of Native American, Native Alaskan, or Native Hawaiian remains on federal or tribal lands; (2) trafficking of Native American or Native Hawaiian remains; and (3) a requirement that federal agencies and institutions or museums receiving federal funding or having any other type of federal involvement assemble Inventories and summaries of their collections for publication in the Federal Register (Mays 2010: 340).

In 1991, the Royal Commission on Aboriginal Peoples was established in Canada which promoted the voluntary return of remains to appropriate First Nations communities (Mays 2010: 335). Ethical guidelines as developed in the Canadian Archaeological Association's 1996 *Statement of Principles for Ethical Conduct Pertaining to Aboriginal Peoples* encourage consultation with indigenous communities on matters relating to heritage, excavation, and human remains (Hanna 2003: 242). Despite these efforts, there is no federal law in Canada which mandates the return of First Nations ancestors or requires repatriation. Henderson (2009: 58) states that the absence of such a law encourages the dismissal and disregard for First Nations perspectives. However, several provinces have heritage statutes that address treatment of human remains. These statues include mandates for protecting inadvertent discoveries of human remains and contacting the nearest First Nations communities once discoveries have been determined to be archaeological (Parks Canada, https://www.pc.gc.ca/en/docs/r/pfa-fap/sec7/decouv_discov3).

In 2006, the Tamaki Makau-rau Accord on the Display of Human Remains and Sacred Objects was adopted by the World Archaeological Congress (see ▶ "Tamaki Makau-Rau Accord on the Display of Human Remains and Sacred Objects (2005)"). Similar to the Vermillion Accord on Human Remains, these six principles discuss the culturally appropriate display of human remains, permissions which should be acquired from indigenous communities prior to research, and frequent consultation between parties to ensure transparency and accurate communication (http://worldarch.org/code-of-ethics/).

The General Assembly of the United Nations adopted the Declaration of the Rights of Indigenous Peoples in 2007, outlining both the collective rights of indigenous peoples and the rights of individuals (United Nations General Assembly 2007). Specifically, Articles 11 and 12 focus on the rights of indigenous communities to protect and develop all manifestations of their culture and control ceremonial objects and human remains for spiritual use and reburial (United Nations General Assembly 2007, Article 11 (1), Article 12 (1). Although this document has no legal enforcement, it reflects the commitment by the international signatories to promote and recognize indigenous parties' right to control and maintain their own cultural heritage.

In 2018, the Department of Arts and Culture within the Western Cape Government of South Africa released the Draft National Policy on the Repatriation and Restitution of Human Remains and Heritage Objects. This document was released in response to frequent requests made to the Government to repatriate the remains of South Africa individuals from South African and international museums (Draft National Policy on the Repatriation and Restitution of Human Remains and Heritage Objects, 2018). It discusses the challenging nature of repatriation and reburial, the management of skeletal remains and cultural items in South African museums, and procedures for making claims (https://www.westerncape.gov.za/assets/departments/cultural-affairs-sport/draft_national_policy_on_the_repatriation_and_restitution_of_human_remains_and_heritage_objects.pdf).

In 2007, the National Committee for Evaluation of Research Involving Human Remains was established in Norway. This was in response to a repatriation dispute between the living Sámi descendants, who asked for return for reburial of their ancestors' skeletal remains curated by University of Oslo's Department of Anatomy (Sellevold 2010: 140). The task of this committee is to consider and deliberate on the ethical considerations for research proposals involving human remains, particularly those of Sámi ancestors (Holand and Somerseth 2010: 21). Similar discussions have taken place in Sweden, where the repatriation and reburial of Sámi ancestors from

Swedish museums is being advocated for by Sámi communities and supported by the Swedish Sámi Parliament (Nilsson Stutz 2007: 1).

For indigenous populations in Australia, the deceased are considered living parts of the community and their reburial is an intrinsic part of spiritual wellness and the health of the relationship between the dead and their descendants (Bienkowski and Coleman 2013: 82–83). Human remains predating 1770 are legally considered to be aboriginal and indigenous groups have been working to remove collections from museums for reburial (Mays 2010: 334). Additionally, indigenous groups to Australia have been lobbying in a concerted effort with the Australian government for the return of Australian aboriginal remains curated in international museums (Mays 2010: 334).

In Israel, reburial efforts are stimulated by religious arguments, with Jewish communities objecting to the disturbance and handling of human remains (Mays 2010: 335). The "Halacha," or Jewish burial law, permits the relocation of human remains as part of salvage operations by the Israel Antiquities Authorities; however, the orthodox Jewish community opposes any excavations on burial grounds and strictly forbids scientific study or anything that might disturb the deceased (Nagar 2002: 87).

However, there are situations when the excavation of human remains is necessary, such as from erosion from climate change or areas slated for construction due to population expansion. In the United Kingdom, the majority of excavated human remains come from rescue or salvage operations ahead of urban development projects (Mays 2010: 336; Sayer 2010: 21). Despite the inevitable removal of these remains, ethical questions still arise regarding how the remains should be excavated from salvage projects, what should be done after they are removed from the ground, or if they should be reburied and by whom (Blau 2014: 2453). Often it is the opinion of the British public which is sought in making decisions about the treatment of remains, and while not uncontested, for the most part the public is supportive of the display of human remains in Britain (Sayer 2010: 96).

In working with collections or in countries that do not have histories of colonialism, codified systems of ethics, or where the treatment of human remains is highly varied, ethical guidelines still must apply. The treatment of human remains must still be respectful and the archaeologist should defer to the local community's definition of what respect is. Archaeologists should educate themselves on the local cultural protocols and histories, to obtain an understanding of the context in which communities develop their own ethical principles.

Additional efforts have been made by global organizations such the British Association of Biological Anthropology and Osteoarchaeology (BABAO), the American Association of Physical Anthropologists (AAPA), the Society of American Archaeology (SAA), and the American Anthropological Association (AAA), which have developed and integrated codes of ethics to guide archaeologists that work with human remains. Other national and international documents such as the Center for World Indigenous Studies' *International Convenant on the Rights of Indigenous Nations*, and the United Nations Education, Scientific, and Cultural Organization's *Convention on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Cultural Property* have also been created to address indigenous rights to their cultural heritage (Hanna 2003: 238; Henderson 2009: 59; Scarre 2013: 667).

Future Directions

Going forward, it is likely that there will be vestiges of discord and disagreement when debating the ethical principles regarding the treatment of human remains. In situations of competing and conflicting ethical systems, Walker (2008) advocates for open communication and understanding to find solutions which are amenable for both parties, as opposed to polemics and "self-righteous posturing" (13). While even among descendant communities, there may not a consensus on the appropriate treatment of human remains (Turner and Andrushko 2011: 44), Henderson discusses how the improved understanding of Indigenous ethics would create opportunities

where communities exercise control over their heritage and their knowledge is respected and consulted (2009: 69).

Martin et al. (2013) suggest three questions every researcher working with human remains should ask prior to conducting their work: (1) What are the full implications of conducting this research? (2) How might the research impact the descendant and local communities? and (3) Are there potentially negative ways the information being collected and disseminated might be utilized by people outside the field of archaeology? (24). Despite their views on the importance of scientific inquiry, researchers working with collections of human remains have been forced to recognize that they share a mutual interest in those collections with indigenous communities and that in order for their work to remain relevant to those outside the discipline, they must consider the belief systems of the descendant populations and reflect on whether or not community members are likely to share the motivations driving their personal research.

Turner and Andrushko encourage the engagement and increased participation of local researchers and students in all aspects of the project in order to promote attitudes of collaboration and equality (2011: 57). They advocate for the dissemination of research findings not only to indigenous stakeholders, but to the general public as well in order to make their work more inclusive and relevant to those outside academia (2011: 57). While many consider this a vital part of any archaeologist's work with human remains to avoid being esoteric and to be able to connect their work with contemporary issues, it is also important to consider the wishes of the local community regarding whether or not any collected data should be disseminated outside of the community (Martin et al. 2013: 23, 25).

Global archaeology is moving towards becoming a more inclusive and participatory science, allowing for the framing of a more comprehensive and encompassing view of the past (Martin et al. 2013: 23). Martin et al. discuss how important the dialogue between native communities and archaeologists is so that the treatment of human remains is as individuals rather than as objects of study (2013: 42). Previously disenfranchised groups now can decide the disposition of their ancestors, which is seen as vital to the survival of indigenous communities (Walker 2008: 16). As Henderson discusses (2009), this is a "moment of possibility," where archaeologists and native communities can learn from one another's views of ethical responsibility and work towards amiable partnerships that are mutually beneficial (67). This type of relationship shifts control away from the archaeologist, so that the community can choose to become a vested partner while controlling the dissemination of their own cultural property (Hanna 2003: 251–252; Henderson 2009: 67–68).

Zimmerman discusses how archaeological ethics are "complicated and ever changing" and reminds us how every paradigm shift within the field is an important and vital process to better understanding the past and moving towards and ethic of collaboration (2012: 99–100). Rather than binaries, there has and will always be a continuum of opinion regarding what defines ethical treatment (Zimmerman 2012: 105). With the incorporation of new research questions, methods, and technologies, previously engrained ethics are being replaced by broader views surrounding collaboration and indigenous stewardship (Zimmerman 2012: 113).

Human Remains: Historic Cemeteries

Amanda Lauren Murphy
University of Manchester (alumna),
Manchester, UK

Introduction

The study of historic cemeteries is a developing subdiscipline of historic archaeology, focused on the material culture and human remains associated with temporally recent burial sites. Historic cemeteries are typically burial places conducting interments following the Judeo-Christian tradition, in Westernized countries and enclaves from the postmedieval period (in Europe, circa 1485 AD) to present (Cherryson et al. 2012; Baugher and Veit 2014). Such burials include those within church buildings and church yards, urban burial grounds, and true municipal cemeteries, as well as those serving historic forts, missions, institutional burial grounds, and family or town plots (ibid.; Cox 1998; Heilen and Gray 2010; Stojanowski et al. 2013).

Outside of Europe the historic period is more variable, depending on when the country in question was colonized or began to modify its burial traditions to conform to western or postmedieval norms. Outliers are to be found in the early exploration and missionization periods. For example, in the United States, missionization occurred in Florida in the late 1500s, with colonization in the northeast occurring in the 1630s (Stojanowski et al. 2013). The first historic burials in Canada likely date to the founding of the fort at Quebec in the 1530s and slightly later settlements in New Foundland. In Australia, historic cemeteries were founded in the 1790s, but burials associated with European exploration likely exist from earlier periods. In short, wherever people lived or traveled, it may be assumed that some people also died and were buried, bringing their burial traditions with them (Cherryson et al. 2012; Baugher and Veit 2014). Archaeologists as well as historians, art historians, and demographers study such sites via survey, the recording of monuments, subsurface testing, and subsurface excavation (Mytum 2000; Cherryson et al. 2012; Baugher and Veit 2014).

Historic cemeteries, despite occupying a relatively narrow and recent temporal range, encompass an eclectic variety of styles and burial behaviors. Classic examples of well-preserved historic cemeteries from the Puritan, Anglican, Catholic, Pioneer, and Victorian traditions include such sites as the Myles Standish Burying Ground, Duxbury; the Boothill Cemetery, Tombstone; Green-wood Cemetery, Brooklyn; the St. Louis Cemeteries, New Orleans; Glasnevin Cemetery, Dublin; the so-called Magnificent Seven cemeteries, London;

and Montmartre, Montparnasse, and Pere Lachaisse cemeteries in Paris (Cherryson et al. 2012; Baugher and Veit 2014). Many notable historic cemeteries, such as the African Burying Ground, New York, now exist solely as subterranean archaeological sites (Cheek and Roberts 2009).

Definition

Historic cemeteries encompass western-tradition human burial places from roughly 1500 to 1950 AD. Broadly, historic burial tradition includes subterranean or substructure burials, in a grave cut or vault, as well as above-ground vault and mausoleum burials (Cherryson et al. 2012; Baugher and Veit 2014; Springate 2014). The historic corpse has typically been prepared for burial via practices which range from washing, dressing, and laying out in the home by family members, to embalming or preparation by a professional undertaker in the later periods (Morely 1971; Gittings 1984). Individuals are usually placed in a wooden or metal receptacle such as a coffin or series of caskets (Springate 2014). They are generally either dressed or wrapped in a winding sheet and interred with a small quantity of personal effects, burial accoutrements, and/or ritual objects (Cox 1998; Baugher and Veit 2014).

Although single interments per receptacle and per grave are the ideal in this tradition, multiple burials also occur with high frequency (Gittings 1984; Cherryson et al. 2012). The marking of a grave's surface with a monument of wood, metal, or stone is often desirable, but unmarked graves and diverse marker-types are also common and normative (Heilen and Gray 2010; Baugher and Veit 2014). Secondary repositories for large quantities of bone, such as charnel houses and catacombs, fall within this tradition in some locales (Cherryson et al. 2012). It also includes cremation in later periods (Gittings 1984).

The time elapsing between death and burial varies highly by time period, social class, and the circumstances of the death. Obsequies range from minimalistic, stoic, and economical, as exemplified by the Puritan tradition; to lavish, effusive, and extravagant, as exemplified by British heraldic funerals and the Victorian Beautification of Death movement (Stannard 1977; Morely 1971; Gittings 1984). A wide variety of burial behaviors exist during the time period, depending especially on cultural background and religious affiliation. Funeral rituals during this time period are sufficiently diverse and nuanced to constitute their own field of study.

Historic cemeteries also include atypical and non-Judeo-Christian burial sites, provided they fall within the historic period, and are not more closely a continuation of another burial tradition under archaeological study. Examples of these diverse traditions and ethnic compositions include slave and freedmen's cemeteries; burial sites for immigrant laborers; Mormon pioneer cemeteries; historic catacombs and charnel houses; the burial sites of indigenous peoples who adopted western traditions; and mission or colonial cemeteries in "nonwestern" countries (Cheek and Roberts 2009; Davidson 1999; Stojanowski 2014). Some types of contemporaneous burials, such as military cemeteries, plague pits, infant cemeteries and Irish cillini, and prison or poorhouse cemeteries, are also considered historic but are frequently subsumed under a different umbrella of study (e.g., conflict remains, osteological studies of disease or poverty) because of their unique demographic characteristics (Mytum and Evans 2002; Grauer and McNamara 1995; Pfizenmaier 2016).

Historical Background

The evolution from medieval churchyard to modern cemetery followed an era of urbanization and sanitation reform (Wilson and Levy 1938; Mytum 1989; Cox 1998; Cherryson et al. 2012; Baugher and Veit 2014). Although occurring on different timeframes in different regions, this shift was generally characterized by an interdiction against intramural burial; closure of overcrowded churchyards; a transition to urban burial grounds; closing of the urban burial grounds; a transition to the garden cemetery; and a final evolution to the lawn cemetery as we know it today (ibid.).

Historically, many factors caused cemeteries to fall into disuse and resulted in the disinterment of

individual bodies (Cox 1998). Following medieval traditions, the earliest interments were found in church yards and the vaults beneath churches: the most prestigious and desirable location. The average plot was "sold" only for a short tenure: disinterment after a period of 5–10 years was followed by permanent interment in charnel houses or mass burial pits (Cherryson et al. 2012; Baugher and Veit, 2014). Multiple stacked burials were common, with some accounts stating that 15 or more people might share the primary grave (Cherryson et al. 2012). Reopening graves to add bodies disturbed those below. The shallow depth of the topmost burial often meant that remains would rise to the surface in the rain (ibid.; Mytum 1989).

Churchyards quickly became overcrowded and unsanitary (Mytum 1989). The result was a series of cemetery reforms that trended towards privacy and permanence in burial. Designated urban burials grounds on the outskirts of developed areas replaced closing churchyards (Wilson and Levy 1938; Mytum 1989; Cox 1998; Cherryson et al. 2012; Baugher and Veit 2014). Attempts were made to legislate factors such as depth of burial and number of interments within a single grave for reasons of public health (ibid.; Cherryson et al. 2012). However, as cities expanded rapidly, overcrowding and sanitation again became issues.

In major urban centers, wholesale attempts at burial ground clearance and relocation to catacombs were taking place in the late seventeen to mid-eighteen-hundreds. Two examples are St. Pancras, London, and Les Innocents, Paris (Cherryson et al. 2012; Boyle 2015). In similar cases in America, relatives responded to newspaper requests that they disinter their loved ones (Heilen and Gray 2010). Increasing mobility also resulted in independent disinterment of recent ancestors to be reburied where their descendants resettled. Theft of bodies for medical dissection was another circumstance leading to disinterment in the historic period (Richardson 1988).

As overcrowded urban burial grounds closed, the transition began to garden cemeteries outside of city boundaries (Cox 1998; Cherryson et al. 2012). During the Victorian period, these rambling, bucolic idylls were a nexus for the cult of mourning, where the living could commune with the dead in a rural setting (Morely 1971; Curl 2001). Following the World Wars, as people began to dwell on death in a more detached way, the modern lawn cemetery with its neat, manicured rows of graves arose (Gittings 1984; Cherryson et al. 2012; Stearns 2015; Lacqueur 2016).

Despite the historic relocation of some cemeteries, and some individual bodies, only small percentages of the total number of urban cemeteries and the total number of burials in any given cemetery appear to have been removed in the historic period in the USA and UK. While the surface features of some historic cemeteries are preserved, many fell into disuse and were forgotten, leaving subterranean features largely intact (Cherryson et al. 2012; Baugher and Veit 2014).

Burial tradition across this time period followed general rules but differed between ethnic groups, religious sects, and region. At the end of the Medieval period, funeral rituals were characterized by Catholic practice which took the form of prolonged intercession for souls presumably in purgatory (Gittings 1984; Cox 1998). Among practicing Catholics, these traditions continued throughout the historic period but were influenced to varying degrees by Protestant fashion.

During the early postmedieval period, two groups broadly characterized Protestant belief and burial tradition: Calvinists, or Puritans, and Anglicans. Without purgatory, anxieties about salvation and resurrection yielded two different deathways. The first was the Puritan horror of the corpse and professed, although not always factual, emphasis on simplicity in burial (Morely 1971; Stannard 1977). The Anglicans, by contrast, developed ostentatious heraldic funerals among the British nobility: a reaction to the finality of Puritan judgment, mingled with an attempt to retain some aspects of Catholicized tradition (Gittings 1984). Embalming arose during this time, due in part to the delay necessary to plan elaborate funerals and qualms about bodily decay (ibid; Richardson 1988).

During the 1600s, the aristocracy reacted to this manipulation of the corpse and the rigidity of burial protocols with the gradual popularization of less ostentatious "night funerals," allowing

them a more personal interaction with grief (Gittings 1984). At the same time, the lower classes were attempting to imitate the upper-classes' previously extravagant burials. This obsession with providing their loved ones with so-called "decent burial" often came at insurmountable personal expense (ibid.; Cherryson et al. 2012; Richardson 1988). During the Romantic and Victorian eras in the mid-seventeen to mid-eighteen hundreds, this fixation had evolved into the "Beautification of Death" movement, characterized by ritualized behavior and objects that idealized death and heaven, as well as prolonging the mourning and memorialization of the dead (Curl 2001).

Historic-period Catholic, Jewish, Africanized, Chinese, and Japanese burial traditions are found with some frequency in the archaeological record, depending on the country of study. These are marked by distinct material culture. Historic Jewish burials are characterized by coffins made without metal, contact with the soil, and burial in a shroud (Sayer 2012). Catholic burials are commonly accompanied by specific religious signifiers such as saint's medals, crucifixes, or floral halos for very young children (Heilen and Gray 2010; Stojanowski 2013). African burials may have associated ritual objects including the last items used by the deceased, or a shoe or plate of salt placed above the corpse (Davidson 1999; Cheek and Roberts 2009). Chinese burials sometimes include secondary interment and may result in archaeological features containing no remains at all. They may also contain more grave deposits, such as money or burnt offerings.

Archaeological study of historic cemeteries typically focuses on bioanthropological analyses of human remains, as well as interpretation of surface and subsurface material culture. Because historic cemeteries often contain abundant remains, the involvement of an experienced physical anthropologist is standard in their excavation and study (Cherryson et al. 2012; Boyle 2015). In addition to providing clues about individual identities and family relationships, the study of large groups of human remains from a single community and time period yields interesting information about pathology, demography, taphonomy, and osteometric and nonmetric traits in osteological populations. The increasing ease of DNA and isotopic studies even allows for a better understanding of topics such as migration and consanguinity.

Despite a wealth of burial traditions, some manifestations of material culture and burial practice are fairly universal to historic cemeteries (Cherryson et al. 2012). Although vaults and mausoleums are historic period features, subterranean interments (i.e., graves) are relatively more common. In certain locales, where, for example, the soil is saturated or rocky (e.g., Louisiana, west Texas), above ground vaults or burial in shallow graves beneath rock mounds may be normative. Despite the wisdom of graves being six feet deep, they vary in depth and dimension. This is contingent on soil quality, and the size of the individual to be buried. Typical subterranean interments are stone or brick lined cists, wooden vaults, or unadorned earthen pits (see Heilen and Gray 2010; Davidson 1999; Cheek and Roberts 2009). Such graves may include bricks, stones, or wooden props to stabilize the coffin during funerals. Objects such as the remnants of rope from lowering the coffin may also be found at their bottom. In some circumstances, burial in a shroud or a winding sheet was used in place of a coffin. Other contexts, such as paupers' pits and plague pits, may tend to include fewer encased burials, resulting in heavily comingled assemblages (Fowler and Powers 2014).

Historic coffins have many shapes but are often a simple rectangular; lozenge-shaped octagonal; or pinch-toe, wide-shouldered hexagonal box (Springate 2014). In later periods, a coffin is often nested inside an ornamental casket. Burial containers, where they are present, range from homemade, unadorned boxes, to mass-produced receptacles with ornamental hardware, lined interiors, and glass viewing windows. Lacquers, colorful paint, or upholstered exteriors were also popular (Heilen and Gray 2010). It is important to note that elaboration does not necessarily equate with price, and style does not neatly equate with date, as mass-produced burial containers and hardware had a long shelf-life in rural communities (Springate 2014).

In addition to human remains and burial receptacles, a number of other associated artifacts are common. Some form of attire is usually present. This may involve a shroud, a special or formal burial garb, or the clothes the deceased died in (Cherryson et al. 2012; Springate 2014). In the case of coffins with viewing windows, formal garb may exist only from the waist up. The joints including the jaw may be bound with cloth or other fasteners to prevent disarray during viewing and burial. Burial goods may constitute personal effects, as well as ceremonial items such as medallions, coronets, offerings, superstitious tokens, or the last objects used by the deceased (Heilen and Gray 2010; Davidson 1999; Cheek and Roberts 2009; Stojanowski 2013). Additionally burial containers may be upholstered or lines with flora, wood shavings, grass, wadded cloth, or even embalming bottles to prop up parts of the body (Springate 2014).

The surviving surface features associated with historic cemeteries likewise contain important information requiring archaeological study (Cherryson et al. 2012). Historic cemeteries are often mindfully landscaped spaces, including paths, fenced plots, occasional buildings, and decorative flora. Understanding the initial placement and movement of these is crucial to locating and interpreting the subsurface features (Mytum 2000; Baugher and Veit 2014). This is crucial as the spatial arrangement of graves may yield important information regarding family, social, and religious relationships, as well as date of death and use-history of the burial ground.

The study of gravestone iconography and manufacture is one of the earliest and most common occupations of historic cemetery archaeology (Dethlefsen and Deetz 1966; Mytum and Evans 2002). Such research provides information about religious beliefs and stylistic developments, as well as biographic and demographic information about the burials within the cemetery. It is important to note that not all burials initially included lasting monuments (Heilen and Gray 2010; Baugher and Veit 2014). Those that do may display incomplete or even intentionally inaccurate data, such as exaggerated age at death to increase the perception of an individual's venerability (Cox 1998). Some graves are completely unmarked from their inception, while others may be situated around a shared monument. Grave markers include elaborate headstones or monuments, simple rough field stones, wooden crosses or other markers, or even bespoke items like bedsteads and seashells (Heilen and Gray 2010; Davidson 1999; Cheek and Roberts 2009; Mytum 2009). As with burial hardware, graves markers and plots may be relatively simple in design, or they may involve footstones, capstones, wrought iron fencing, and other material culture.

Key Issues/Current Debates

Rapid changes in burial behavior and frequent site abandonment make historic cemetery studies a complex process. Much historical research has focused on the iconography and content of cemetery monuments from an art-historical perspective (Dethlefsen and Deetz 1966; Mytum and Evans 2002) and the social beliefs surrounding death (see Morely 1971; Stannard 1977; Gittings 1984; Richardson 1988).

True archaeological studies pertaining to the surface and subsurface material culture of historic cemeteries are gradually becoming dominant, and much of the work remains descriptive (e.g., Strangstad 2013; Mytum 2000; Stojanowski 2013; Baugher and Veit 2014). Many isolated excavation reports seek to elucidate the history of a particular site or answer questions of local historic interest (e.g., Miles and White 2008; 2015; Heilen and Gray 2010; Cheek and Roberts 2009; Davidson 1999). In the United States, many of the larger excavated cemeteries have been burials of slaves or freedman, so regional questions pertaining to the institution of slavery are common (Cheek and Roberts 2009; Davidson 1999). In the United Kingdom, the study of pathological conditions, such as mass plague burials, has been another major theme of study (Walker 2012; Fowler and Powers 2014).

Few works have focused on general issues related to the subsurface archaeology of historic cemeteries (e.g., Baugher and Veit 2014). The material culture of burial furniture is one area

which is beginning to receive attention (Springate 2014). As with most sites involving human burials, the ethics and legality of excavating human remains is another issue which is emerging, as more forgotten historic cemeteries are rediscovered and relocated (Sayer 2012; Ubelaker 2011; Boyle 2015).

Much ongoing research into larger questions explores whether written records from the historic period can be substantiated by the material culture of cemeteries and the human remains found within them (e.g., Grauer and McNamara 1995). Issues of demography, taphonomy, and pathology are among the more common topics. Comparative studies between poorhouse cemeteries are among these, as well as demographic studies exploring the suitability of historic cemeteries as comparative samples for taphonomic changes in bone (Grauer and McNamara 1995; Murphy 2016; Murphy and Chamberlain 2017). Historic cemeteries are uniquely suited to answer questions regarding the decomposition rates of human bodies, cause-specific mortality, attitudes toward death, historic burial traditions, and historical disease and trauma. This is because they contain human remains as well as material culture, which can often be compared to written records.

International Perspectives

What is considered to be of archaeological interest varies by country, as well as the legal process for dealing with recent burials, and the frequency with which they are encountered. Therefore, the concept of historic cemetery archaeology may be more common in westernized traditions, where historic period burials are distinct from older burial practices, and where it is more likely they will be excavated archaeologically. In studies of global funerary traditions in the modern era, many Asian, African, and Middle Eastern cultures have shown more continuity in burial practice (Stearns 2016). Countries such as Mongolia experienced a reversion to traditional deathways. Other countries such as Ghana have integrated unique modern adaptations to local traditions yet diverge drastically from and in many ways defy the "westernized" historic cemetery with its increasingly medical management of death (ibid., Laqueur 2015). Such practices contrast with the western shift towards the emotional depersonalization of death and prolonged mourning, as cemeteries themselves moved ever farther away from the sphere of the living.

Historic cemetery excavation often occurs in cases where such sites have been forgotten and rediscovered during construction (Baugher and Veit 2014; Boyle 2015). In locales with firmer religious-based burial laws (e.g., Scotland), regions where cemeteries were moved historically to catacombs (e.g., France), or areas with an abundance of space (e.g., Australia and rural parts of America), historic burial excavation remains uncommon (Cox 1998; Cherryson et al. 2012). This is because inadvertent disturbance may be rarer, and it may be considered inappropriate to excavate human remains when it occurs.

Many countries outside of the United States have an archaeological focus that is very ancient. The historical period may be neglected in these regions. Furthermore, the concept of the historic cemetery as a unique archaeological landscape may not exist where burials follow a continuous tradition. Therefore, they may be considered within a different subdiscipline, where they are studied at all. In these and other instances, the relocation of historic graves may be considered the provenience of funeral homes (Boyle 2015).

As the field expands, it is hoped that more comparative studies are made surrounding the variations in global deathways in response to the events of the eighteenth to twentieth centuries, integrating unique regional deathways, which are no less fascinating, but which may be initially perplexing to study under the same umbrella.

Future Directions

In the majority of cases, historic cemeteries are excavated not solely for academic study, but because their accidental discovery during construction necessitates it (Baugher and Veit 2014). Such cemeteries may be relocated by exhumation contractors, private cultural resource management firms, or academic excavations (Boyle 2015). This results in uneven treatment of the sites and

irregular collection of data no matter their archaeological significance. The laws dictating the treatment of historic burials also vary by country and by region, so the ethics of excavating cemeteries to an acceptable archaeological standard is a growing issue (Ubelaker 2011; Sayer 2012; Boyle 2015).

The ethical excavation of a historic cemetery is complicated by the fact that they are often discovered unexpectedly and contain a large number of surface and subsurface features (Ubelaker 2011; Cherryson et al. 2012). As each burial also represents the remains of a human being, potentially with living descendants, respectful treatment is preferable (Sayer 2012).

Unfortunately, because of their complexity, their excavation may need to be particularly slow in instances when development interests would prefer that they progress rapidly. Often, the sites encompass long use-periods (Boyle 2015). Many historic cemetery areas had dual functions as agrarian, religious, or social spaces, followed by periods of historic disuse, overbuilding, and modern repurposing (Cox 1998; Cherryson et al. 2012). Cemeteries are often heavily disturbed, due to their urban histories and the historic changes that brought about the development of the modern cemetery in the first place.

Because historic disturbances are typical, it has sometimes been assumed that cemeteries are unlikely to contain human remains after around 100 years, so there will be no subsurface archaeology left to consider (Batillo 2012). This is false. Even the oldest historic burials and many disturbed cemeteries contain well-preserved human remains, as well as material culture associated with the burials (Baugher and Veit 2014). "Airtight" Fisk caskets and other unique environmental circumstances sometimes may even result in the preservation of soft tissue (Springate 2014). Because of these factors, historic cemeteries are interesting not only for the information they yield about their time period and communities, but because they are well preserved osteological datasets which also may be large and complex.

As the issues pertaining to their excavation become more well known, and the data potential of such large osteological datasets with associated demographic records becomes better appreciated among archaeologists, it is expected that better standards of methodology and recording will result (Murphy 2016; Murphy and Chamberlain 2017). This should be accompanied by legislation stipulating the treatment of disturbed burials (Batillo 2012; Sayer 2012). Additionally, as the historic period moves farther away from the present, the study of historic sites in general is likely to become relatively more common.

Identification Defined

Identification is defined as the act of establishing an identity that makes an entity definable and recognizable (Black 2007; see also Latham et al. 2017; Mallett et al. 2014). While identification may be important in cases involving the living (e.g., Black et al. 2010; Blau et al. 2006: 387), in archaeological and forensic cases, identification involves attributing a correct name to human remains. There are various circumstances where there may be a requirement to establish the identity of a deceased individual: following an unexplained natural death, homicide, suicide, or accident; in cases of death following political, ethnic, or religious violence; and mass disaster incidents. The attempted identification of historic figures has also been pursued (Blau et al. 2014; Bogdanowicza et al. 2009; Clark 2011; Stone et al. 2001).

While the cause and manner of death can be determined independently of identification, the absence of the name of the deceased person means there is no way to know who to talk to collect information about the person when they were alive (antemortem data) and therefore confirm or deny identification. The identification of a deceased person is important for a variety of legal, religious, cultural, and ethical reasons (Blau and Hill 2009). In fact, it has been argued that "[i]dentification of human remains is . . .as important as the collection of evidence for criminal investigations. It is a duty of investigators, in recognition of the right to know of concerned families, as enshrined in international

humanitarian law" (Tidball-Binz 2006: 389). Essentially, "human beings have the right not to lose their identity after death. . ." (Interpol 1996).

Identification Methods

The identification of a deceased person, whether a historic figure or recovered from a forensic context, is complex and often time-consuming. The process involves comparing information obtained from the analysis of the deceased person (postmortem data) with information obtained about the person when they were alive (antemortem data).

The forensic sciences play an integral part in the identification of deceased individuals. Decisions about which specific techniques to use in the identification process will, however, be influenced by variables such as the preservation and condition of the remains. Accurate and professional recovery of the remains is therefore paramount to ensure that as much information as possible is available to aid the identification process. In addition, the accuracy and quality of the antemortem information are also important variables in the identification process.

Positive Identification

International standards promote the positive identification of individuals. A positive, that is, confirmed identification is achieved when it can be demonstrated that there are enough unique data markers to conclude that the ante- and postmortem records are from the same individual. The primary methods of identification (or unique data markers) include fingerprints, DNA and dental comparison.

Presumptive Identification

In cases where no adequate antemortem records exist (e.g., in countries where people rarely visit a dentist or where fingerprints records are not routinely collected), it may only be possible to establish a possible or presumptive identity (e.g., Simmons and Skinner 2006). While no single factor alone justifies the identification, information such as age at death, sex, stature, associated clothing, jewelry, documents, etc., when considered together, are sufficient for a possible identification.

Exclusion

There will be some cases where the post- and antemortem information do not match, therefore resulting in an exclusion. For example, human remains are located in an area near where missing persons' files indicate that a 15-year-old girl was last seen alive. An analysis of the human remains indicates the individual was an elderly male. Thus, the results of the analysis allow the investigators to exclude the hypothesis that the remains are those of the missing teenager and seek other evidence to form a new proposition for identification.

Variables that Influence the Identification Process

It is important to recognize that the identification process is influenced by a number of variables:

- **Quality of the recovery of remains (completeness)**: In cases where the body is badly decomposed or fully skeletonized, unprofessional recovery may result in incomplete remains where essential parts for analysis and comparison (e.g., teeth) are missing.
- **Preservation/condition**: While the remains may be complete, differential preservation and the condition of the remains will affect the methods which can be considered for identification. Different techniques will be used depending on whether the individual is recently deceased (e.g., a fresh body) or whether significant time has passed (fully skeletonized). For example, a recently deceased person is typically visually identifiable, but it is not possible to use fingerprints for identification when the individual is fully skeletonized. Postmortem and/or perimortem trauma may affect the condition of the remains: in the case of a bomb blast with associated fire, it is possible that the dentition and DNA may be affected.

- **Quality and amount of antemortem data**: There may be cases where only general information such as the age and sex of the person is available, which does not provide enough detail for individualization. The nonexistence of or inability to locate medical and/or dental records may also make it impossible to reach a positive identification. In many instances, there will be no available information about what the deceased person was last wearing, i.e., their clothing and/or personal belongings.
- **Open or closed case**: A closed case refers to a situation where the exact number of missing individuals is known. An example is a plane crash where details of the number and names of people on the plane would have been submitted prior to flight departure. Following the disaster (whether accidental or human-induced), it is therefore possible to define the exact number of missing people and formulate a list of names of victims for which to obtain antemortem data. In contrast, an open case implies the exact number of individuals lost as a result of the disaster or atrocity is unknown because no manifest of missing persons exists. Terrorist bombings, tsunamis, earthquakes, public transport, and ferry disasters are all examples of open cases. In general, the number of persons reported to authorities as missing will exceed the actual number involved in the incident.

Cases Where Remains Cannot Be Identified

There will be situations where remains cannot be identified at the time of the investigation whether as a result of inadequate or absent antemortem data or a lack of resources which result in the inability to form an identification hypothesis. Decisions must then be made by the institution/organization responsible for the remains as to how to appropriately store the remains securely until new information or resources become available (e.g., Cordner et al. 2016).

Summary

The identification process involves the evaluation and integration of all available information. A successful outcome may be achieved through a multidisciplinary approach in which an assessment of the contextual information is taken into account. Whether resulting in a positive or presumptive identification or an exclusion, all available information must be assessed by the relevant experts. The choice of method used to identify an individual will depend on the context of the death of the person, preservation of the deceased, access to antemortem information, and available resources (e.g., DNA capabilities) (Blau and Hill 2009).

Hunter-Gatherer and Midrange Societies: Uluṟu

Melissa Marshall[1] and Michael Starkey[2]
[1]Nulungu Research Institute, The University of Notre Dame Australia, Broome, WA, Australia
[2]Kokatha Aboriginal Corporation, Port Augusta, SA, Australia

Introduction

Uluṟu (also known as "Ayers Rock" or "The Rock") is a sandstone monolith in the center of Australia. Uluṟu is located within the Uluṟu-Kata Tjuṯa National Park approximately 350 km southwest of Alice Springs and 4 km from the Ayers Rock Resort in the township of Yulara (Figs. 1 and 2). The surrounding environment consists of an extensive system of sand plains, dunes, and alluvial desert (Austral Archaeology 2006: 5). This landscape contains extensive archaeological sites and cultural material including numerous rock art sites, artifact scatters, camp sites and areas of occupation, grinding grooves, scared trees, and sites of historical significance. Uluṟu is an extremely significant and important place for the local Aboriginal group of Aṉangu people, who are guided by their Tjukurpa (traditional law) and continue to live there in the nearby community of Mutitjulu. Aṉangu means "people" in Yankunytjatjara and Pitjantjatjara, and today Aṉangu people proudly manage the National Park jointly with the Australian government. In 2015, Aṉangu celebrated 30 years since the official handback of these lands to Aboriginal people. According to Aṉangu elder T. Tjamiwa, the Park is like a table with one leg unless it is underpinned by Aboriginal law and ownership (Hill 1994: 7); stability comes from this.

Definition

The site of Uluṟu is a sandstone monolith, 9.4 km in circumference and in excess of 340 m high (Department of Environment 2008). The site obtains its name from the local Aṉangu people, who have practiced their culture, and continue to do so, in and around the site for millennia. Uluṟu is also commonly known as "Ayers Rock" on account of the first European to sight it and who named it, thus, the explorer William Gosse in 1873. Located within the Uluṟu-Kata Tjuṯa National Park (UKTNP), Uluṟu is in an area of Central Australia on the southwestern margins of the Lake Amadeus sedimentary basin (Hardy and Johnson 2006: 22). Thirty-two kilometers to the west of Uluṟu lie the 36 sandstone domes of Kata Tjuṯa (meaning "heads many" in the local language of Pitjantjatjara). This site is also known as "The Olgas" as referenced by Ernest Giles in 1872 after the then Queen of Württemberg.

Hunter-Gatherer and Midrange Societies: Uluṟu, Fig. 2 Changing colors of Uluṟu (With kind permission of Uluṟu-Kata Tjuṯa National Park)

UKTNP was inscribed on the World Heritage List in 1987 for outstanding universal natural values and in 1994 for outstanding universal cultural values (Department of Environment 2008). This site was also listed on the National Heritage List of Australia in 2007. Both sites will be referred to by their Aṉangu names only throughout the rest of this entry.

Key Issues/Current Debates/Future Directions/Examples

This following information provides particulars about the site of Uluṟu – the environmental setting, the Aṉangu people, and the archaeological landscape. While this information is thorough, references are also contained below for additional and more comprehensive details.

The Environmental Setting

The landscape surrounding Uluṟu is dry and harsh due to the semiarid environment it lays within, containing complex dune systems, alluvial plains, abundant wildlife, and numerous vegetation species. UKTNP itself covers an area of approximately 1325 km^2 (UKTBoM and Parks Australia 2000: 3). The environmental context of the area is best described with discussion of the geological features, soil landscapes, climate and hydrological data, and the presence of specific vegetation, flora, and fauna species (Fig. 3).

The geological features of both Uluṟu and Kata Tjuṯa are classed as surface expressions of Mt. Currie conglomerate of Cambrian age, an arkose variant of the conglomerate, feldspar-rich sandstone (Hooper et al. 1972). Local outcrops of calcrete are found in the area and stone sources suitable for flaked tool manufacture including quartz, silcrete, and quartzite which are also regionally available (Hardy and Johnson 2006).

The landscape around Uluṟu contains three primary land systems as described in Allan (1984), while only two of these are detailed in Hooper et al. (1972). The first of these is the Gillen Land System, consisting of the sandstone ranges, their narrow gorges, gullies and creek lines, and associated gently sloping fans and alluvium of coarse-textured soils. These are surrounded by the Karee Land System that consists of the gently sloping plains fringing the fans and alluvium of the Gillen Land System. The final major land system covers most of the UKTNP and is the Simpson Land System, consisting of sand plains and dune fields (Austral Archaeology 2006; Hardy and Johnson 2006).

The climatic conditions and subsequent hydrology surrounding Uluṟu are what is to be expected within a semiarid environment. The average rainfall is around 220 mm in a year, and there is no predictability in the variation from year to year (Hardy and Johnson 2006). It is not unknown for rainfall to be over 500 mm for 3 years in a row and then 100 mm for the next 3-year period (Latz 2004). As the annual rainfall is quite low, movement of surface water is localized to within the park (Hooper et al. 1972).

Hunter-Gatherer and Midrange Societies: Uluṟu, Fig. 3 Flora and fauna found within the UKTNP (With kind permission of Uluṟu-Kata Tjuṯa National Park)

As Uluṟu lies within the Great Sandy Desert bioregion of the Northern Territory (Connell 2004), the vegetation present is one that exhibits tolerance to a semiarid environment. Austral Archaeology (2006: 5–6) lists a number of references for the floristic and vegetation patterns around Uluṟu. These include examples from Buckley (1981a, b), Allan (1984), Griffin (1984), Saxon (1984), and Reid et al. (1993). The vegetation present changes with the soil

H

landscapes, moving from sandy to heavier red earths and the alluvial fans and plains. The majority of vegetation present is within the sandy soil landscape and reportedly includes species such as spinifex *(Triodia basedowii* or hard spinifex, *T. pungens* or soft spinifex, and to a lesser extent *Plectrachne schinzii* or feathertop spinifex), desert oaks *(Allocasuarina decaisneana)*, umbrella bush or sandhill wattle *(Acacia ligulata)*, honey grevilleas *(Grevillea eriostachya* and *G. juncifolia)*, desert hopbush *(Dodonaea viscosa)*, cassia *(Senna artemisioides)*, long-leaved desert fuchsias *(Eremophila longifolia* and *E. willsii)*, and the parrot pea *(Crotalaria cunninghamii)* (Austral Archaeology 2006). Within the other soil landscapes, there are also numerous species of mulga present *(Acacia aneura* and related species, as well as sandhill mulga *(Acacia ammobia))*, mallee eucalyptus, bloodwood *(Corymbia opaca)*, corkwood *(Hakea suberea)*, and witchetty bushes *(Acacia kempeana)*, as well as witchetty bushes, native fuchsias *(Eremophila gilesii* and *E. latrobe)*, native currant *(Canthium latifolium)*, cassia *(Senna artemisioides)*, woolly butt *(Eragrostis eriopoda)*, prickly wild tomato *(Solanum quadriloculatum)*, caustic bush *(Euphorbia tannensis)*, and a variety of grasses (Austral Archaeology 2006).

Faunal species present around Ulu̱ru include numerous species of reptiles, kangaroos, and other mammals, birds, and insects. A total of 46 species of native mammal are known to have existed in the area of UKTNP, although this is now reduced (Hardy and Johnson 2006). Currently the range of fauna within the park includes 178 birds, 77 recorded species of reptiles and amphibians – including 60 lizards, 13 species of snakes, and 4 frog species – and 21 mammal species (Department of Environment and Heritage 2012). A full list of mammal, reptile, and bird species present within the UKTNP and information (including A̱nangu names) can be found at http://www.environment.gov.au/parks/ulu̱ru/nature/fauna.html.

A̱nangu: The People and the Park

The A̱nangu are the local indigenous inhabitants of the area within and around Ulu̱ru-Kata Tju̱ta National Park. They are the traditional owners of the area and site custodians of the many sacred and special places located around the base of Ulu̱ru. Many live in the nearby Mutitjulu community, located on the eastern side of the great monolith and not far from the park headquarters and visitors center on the southwestern side. They also speak Pitjantjatjara and identify with the Pitjantjatjara/ Yankunytjatjara language group, with connection not only to this country but also to that to the west and south of the park in the "A̱nangu Pitjantjatjara Yankunytjatjara (APY) Lands."

Long-recognized for their connection to the country, the following extract for the UKTBoM Plan of Management (2000: xx) illustrates this:

> As a cultural landscape, the Park as we know it today represents the work of A̱nangu and nature throughout thousands of years. The landscape of the Park has been managed over this time using traditional A̱nangu methods governed by Tjukurpa, which is A̱nangu law. The Park contains some outstanding examples of the habitats of rare desert flora and fauna as well as the major geological features of Ulu̱ru and Kata Tju̱ta.
>
> A̱nangu believe the Park landscape was created at the beginning of time by ancestral beings and A̱nangu are their direct descendents and have lived here ever since.

A̱nangu take seriously their responsibility to look after the country. The history of the park has been one of struggle and survival, as they battled with many areas of government to manage their own country. In 1985, through their determination, their rights were acknowledged with the then governor-general formally granting title to the park to the Ulu̱ru-Kata Tju̱ta Aboriginal Land Trust (UKTBoM 2000: 9). Today, the park is leased back to the Australian government in a joint management arrangement between the parties.

Underpinning this arrangement is the vision of the Board of Management and this guides all of the work undertaken within the park (UKTBoM 2000: x):

> The Ulu̱ru-Kata Tju̱ta landscape is and will always be a significant place of knowledge and learning. All the plants, animals, rocks, and waterholes contain important information about life and living here now and for all time.

> Aṉangu grandparents and grandchildren will always gain their knowledge from this landscape.
>
> They will live in it the proper way. This is Tjukurpa.
>
> Together we will apply Aṉangu Tjukurpa and practice and relevant Piṟanpa [nonindigenous] knowledge to:• Keep Tjukurpa strong.
>
> - Support a healthy Aṉangu culture and society.
> - Look after country and protect a national symbol.
> - Protect World Heritage natural and cultural environments of the Park in harmony with Australian social and economic aspirations.

The responsibility in caring for the country is innate for Aṉangu, and with this comes the knowledge relating to resources and the use of certain areas for different activities. Resource variations can be identified by the different zones categorized by Aṉangu and include *puḷi* (rocky country, e.g., Uluṟu), *puṭi* (shrub land), *karu* (creek lines and runoff plains), *tali* (sand dunes), *pila* (spinifex plains and low areas between sand dunes), and *nyaṟu* (recently burnt country) (DEH 2006 in Hardy and Johnson 2006).

Management of the landscape relates to these zones and the vegetation types found within them. With practices proven over thousands of years, sites are looked after and managed with intricate fire regimes, the cleaning of waterholes, and other land management practices that help to control the environment and keep the land healthy (Hardy and Johnson). The use of fire is an integrally important part of maintaining the country, and Aṉangu are taught the correct way to burn and manage fire by their grandparents according to Tjukurpa (Muṭitjulu Community 1996: 49).

Aṉangu knowledge also enables people to travel through the landscape, utilizing resources as they move vast distances. Hardy and Johnson (2006) list the known uses of plants and resources in the area that have included:

- Food – seeds, fruit, greens, saps, and tubers
- Medicine
- Wood for making implements
- Water
- Resins/glues
- Fiber
- To aid in hunting/poison
- Ceremony and art
- Decoration
- Toys
- "Native tobacco"
- Shelter

Cultural traditions are strong within UKTNP and are still practiced today by Aṉangu people. The principles guiding this culture are known as "Tjukurpa." It is not restricted to dreaming stories or places. It is all encompassing and includes, but is not restricted to, language, rules of behavior, kinship systems, and the general guiding principles needed for life. Tjukurpa surrounds you when visiting, working, or living in UKTNP.

Tjukurpa is central to life at Uluṟu – it is the law, and it is the dreaming, the story, and the message (Mick Starkey 2006, personal communication). Aṉangu see Uluṟu and Kata Tjuṭa as part of a cultural landscape and reference is to the spiritual meaning of the park, and spiritual interpretation of the landscape, including geological features such as rock faces, boulders, and waterfalls, contains spiritual meaning. All plants and animals derive from the creative period of Tjukurpa as well (Austral Archaeology 2006).

Johnson (2006) writes that there is much evidence of Tjukurpa within the rock art sites around the base of Uluṟu. This includes representation of the stories of *Kuniya* (Woma python) and *Liru* (poisonous snake), as well as *Kurpany* (the spirit dog). Other motifs at public sites, such as those along the Mala Walk on the western side or near the Mutitjulu Waterhole on the southern side, include symbols for traversing waterholes in the surrounding country, as well as tracks of different types of animals such as the *mala* (rufous hare wallaby), *malu* (kangaroo), and *kaḷaya* (emu) (Figs. 4 and 5). Piti (large wooden bowl) and other manufactured goods are also evident. Through the process of working together, the piranpa (white people) can learn about Tjukurpa from the Aṉangu rangers and traditional owners, all guiding and learning from each other about their ways. There are a number of cultural protocols to work within the sites to ensure that Tjukurpa is looked after (Johnson 2006).

"Sorry Rocks"

A phenomenon that Aṉangu and the Park also have to manage is that of "Sorry Rocks." Since visitors first came to Uluṟu, many have taken pieces of the "Rock" home with them as souvenirs, only to find that this often brought "bad luck." Returning the rocks back to the landscape from which they came and apologetic letters accompanying them is what gave the souvenirs their name of "Sorry Rocks."

Hunter-Gatherer and Midrange Societies: Uluṟu, Fig. 4 Tourists visiting the Mala Walk near The Climb (With kind permission of Uluṟu-Kata Tjuṯa National Park)

Hundreds of these Sorry Rocks have since been returned to the Park, providing Aṉangu and staff alike with a challenge for how to manage these. Foxlee (2008: xvii) examined this phenomenon and challenge as part of her doctoral research, stating that "For Anangu and Parks Australia, the sorry rock phenomenon presented a management issue and an interpretive challenge. The rocks belong at Uluṟu, not in the pockets and homes of visitors. While the return of such objects was welcomed, there was no simple solution for managing the temporary collection of these materials. The analysis of the sorry rock letters demonstrates that people removed rocks and sand from the Park to remember their experience, and as a means of engaging with the place on a personal level. In extreme cases, the lives of certain individuals who engaged in souveniring behaviour were physically and emotionally transformed by experiences of misfortune and loss. For some, the return of souvenired objects was undertaken: out of respect for the traditional owners of Uluṟu-Kata Tjuṯa National Park; as an opportunity to

Hunter-Gatherer and Midrange Societies: Uluṟu, Fig. 5 Rock art on the Mala Walk (With kind permission of Uluṟu-Kata Tjuṯta National Park)

apologise; and as an attempt to make amends for actions of the past."

In her research, Foxlee used the Sorry Rocks as a medium for examining the complex relationships that exist between visitors, heritage management, and interpretation particularly in cross-cultural settings that recognize indigenous cultural heritage (Foxlee 2008: xvii). Today, many of the rocks are now on permanent display in the Park, providing an insight into the phenomenon and encouraging others who may consider souvenirs of their own, to consider the impact this has on Aṉangu, the cultural landscape, and their own lives.

The Archaeology

It is rather surprising that, however enchanting Uluṟu may seem, it has been the focus of only a limited amount of archaeological research, and these have predominantly been in the form of archaeological surveys either for UKTNP reference (Haskovec and Sullivan 1987; Haskovec 1989, 1991) or commissioned in response to development within certain sections of the park and required for management considerations (Thorley 2000; Austral Archaeology 2004; 2006; Hardy and Johnson 2006; Gunn 2007). This in part has been due to the concerns Aṉangu have expressed regarding archaeological excavations in their country both within and outside the park boundary, as this practice is not in keeping with Tjukurpa. The resulting research undertaken has focused solely on surface material culture remains and this is what is discussed here.

The types of sites recorded around Uluṟu have included rock art (paintings and petroglyphs), artifact scatters, campsites, and isolated artifacts (Thorley 2000; Austral Archaeology 2004; 2006; Hardy and Johnson 2006). The majority of artifacts recorded have been made of quartz and were flakes, cores, and flake fragments with isolated instances of silcrete, sandstone, and "tuff" flakes also recorded (Hardy and Johnson 2006: 31). All of the studies in question identified areas of high.

archaeological potential in and around the base of Uluṟu. Discussions with Aṉangu also indicated specific patterns of occupation and land use that included the area between the base of the rock (including shelters) and the first row of dunes (Austral Archaeology 2004). The resulting predictive general distribution model implies that occupation would have been focused on the areas at the base of the rock due to the available water and shelter from the weather and that this would have led to a greater density of artifacts being deposited, with the areas of the sand plains and dunes beyond used for hunting and foraging, potentially resulting in the deposition of a smaller number of artifacts in discrete activity focused areas (Hardy and Johnson 2006: 31).

Looking further afield to obtain a regional context, excavations have been undertaken in the MacDonnell Ranges near Alice Springs providing evidence of occupation in the Australian Arid Zone for minimally the last 22,000 years as evidenced by the presence of flaked stone artifacts, intact hearths, charcoal, grindstones, ochre, and emu eggshell (Austral Archaeology 2006). This excavation recorded periods of intensified occupation approximately 6000 years ago with the periods of most intensive use in the upper layers dating to post 1900 years ago (Smith 1987: 10 in Austral Archaeology 2006).

There continues today strong cultural connections between Aṉangu and the Arrernte people of the Central Desert and other communities to the north, south, east, and west. This is illustrated in shared stories, such as those of ancestral beings that have travelled in and around Uluṟu. This site, and that of Kata Tjuṯa, not only represents a meeting point, but both are important nodes in a great web of Tjukurpa paths (Breeden 1996: 19). Respectively, these paths have come from and spread out across the landscape linking the Aṉangu and Uluṟu-Kata Tjuṯa National Park to the wider communities and surrounding landscapes (Austral Archaeology 2006).

These stories are seen as part of the living landscape around Uluṟu in the form of the rock art present at locations such as the Mutitjulu waterhole and along the Mala Walk (Fig. 6). The battle between Kuniya and Liru is played out on the walls of the waterhole and retold in the paintings at the rock-shelter nearby (Fig. 7). Kurpany also appears here, and at other locations along the Mala Walk, as his travels took him around the

Hunter-Gatherer and Midrange Societies: Uluṟu, Fig. 6 Mutitjulu waterhole (With kind permission of Uluṟu-Kata Tjuṯa National Park)

Hunter-Gatherer and Midrange Societies: Uluṟu, Fig. 7 Rock art at Mutitjulu (With kind permission of Uluṟu-Kata Tjuṯa National Park)

rock. There are images of other Tjukurpa stories, maps for travelling through country from waterhole to waterhole, and one shelter referred to as "The Old Folks Home" where the elders used to sit with the young ones and teach them (Starkey 2000, personal communication). The paintings have been recorded in detail most recently by Gunn (2000) and Johnson (2001), and UKTNP undertakes a cultural heritage maintenance program with Aṉangu rangers leading the way, guided by their cultural knowledge and that of the elders, and learning the western scientific conservation and management strategies to support it.

Despite the acknowledged importance of Uluṟu by Aṉangu, other indigenous groups, and nonindigenous people of Australia,

archaeological research in and around Ulu̱ru as well as the greater UKTNP is limited. Under the guidance of A̱nangu and in keeping with Tjukurpa, further research is required to investigate land use patterns around Ulu̱ru and Kata Tju̱ta, as well as the broader landscape.

Hunter-Gatherer Settlement and Mobility

Matt Grove
School of Archaeology, Classics and Egyptology, University of Liverpool, Liverpool, UK

Introduction

The study of hunter-gatherer mobility operates at the intersection of archaeology and social anthropology, with much information to be gained from both individual ethnographies and syntheses that extract recurrent relationships between the mobility pattern and, for example, the subsistence base. For reasons of brevity this entry focuses on insights obtained from the latter, though the reader is encouraged to consult original studies of particular societies, particularly when such societies do not appear to fit the generic patterns described. Hunter-gatherer mobility operates at various scales, and although it is motivated primarily by the need to gain adequate food and water, it is also shaped by the presence of other resources such as raw materials and of other human groups in the landscape.

Definition

For the purposes of this entry, hunter-gatherers can be defined as individuals who obtain most of their food from the hunting of wild animals and the gathering of wild plant foods. That the previous sentence reads *most* and not *all* is primarily due to the post-contact situation in which hunter-gatherers may live on *reservations*, receive government rations, or trade or exchange goods with neighboring agricultural populations. Mobility is here understood widely to include movements of individuals around a camp, movements of whole groups between camps, and forays into lands inhabited by related but distant groups of hunter-gatherers for purposes of trade, exchange, or knowledge acquisition. These three scales of mobility (which may in fact frequently overlap) are defined here as the micro-, meso-, and macro-scales, respectively.

Historical Background

The study of hunter-gatherer groups by anthropologists dates back to at least the nineteenth century, while the modern era, making explicit the study of modern hunter-gatherers as a means to elucidate aspects of the human past, was initiated by the seminal 1968 *Man the Hunter* volume, edited by Richard Lee and Irven De Vore (1968; see Myers 1988). The studies of Lee's Harvard group among the!Kung San of the Kalahari, many of which were reported in this volume, examined the hunter-gatherer way of life as a phase in the prehistory of all human groups and thus adopted an implicitly (and occasionally explicitly) evolutionary approach to the study of hunter-gatherer mobility. The evolutionary approach has persisted in the form of socioecological analyses and applications of optimal foraging theory, whereby models of the mathematically derived *optimal*

behavior in given situations are compared to actual behaviors in those situations. Evolutionary approaches have been particularly effective in allowing for the formation of general rules about hunter-gatherer adaptation that can be applied to analyses of the archaeological record.

Man the Hunter established an archetypal picture of hunter-gatherers in which males hunted, females gathered, and food was transported back to a *home base*, where it was shared among families or between close kin. This pattern of a sexual division of labor and the transport of food to a home base for sharing was quickly assimilated by archaeologists, particularly in M. D. Leakey's hugely influential publication of the earliest archaeological sites from Olduvai Gorge, Tanzania. Leakey developed a site typology for the Olduvai material in which one of the four site types, labeled the *living floor*, was a direct equivalent of the anthropologically documented *home base*. This typology was modified for the material at Koobi Fora (Kenya) and was then amplified into Isaac's (1978) *home base hypothesis*, which extrapolated from the site typology to suggest that many of the social facets documented among the! Kung were in fact present among two-million-year-old human ancestors.

The *home base hypothesis* attracted many detractors due to its extrapolations from the archaeology. Foremost among these was Lewis Binford, whose attempts to discredit Isaac's ideas led him to focus on the development of ways to relate the static patterns observed in the archaeological record to the dynamic processes in past societies that generated those patterns. A key element of this research program was ethnoarchaeology – the conduct of essentially anthropological fieldwork by archaeologically trained practitioners. Although Binford and many others had noted the value of published ethnographies, they were also aware that ethnographers were unlikely to collect data in forms amenable to comparison with archaeological data; specifically, the pattern-process link was absent, with ethnographers focusing relatively little on the use of everyday artifacts. Binford's studies of hunter-gatherers were conducted with a view to documenting archaeologically salient information and ushered in a new enthusiasm for hunter-gatherer studies among archaeologists.

Key Issues

Microscale Mobility

One of the enduring legacies of Binford's ethnoarchaeological work among the Nunamiut (Inuit) of northern Alaska was the establishment of the forager-collector continuum to describe differences in hunter-gatherer microscale mobility patterns. Foragers and collectors in Binford's (1980) terms were distinguished primarily by their settlement systems and therefore by the types of sites they would leave in the archaeological record; however, these systems also reflected fundamentally different types of mobility in terms of the way those site types articulated with the available subsistence resources (Grove 2010). Foragers are associated with high *residential mobility*, in which the whole group is moved from one camp to another, whereas collectors often practice higher levels of *logistical mobility*, in which task-specific subgroups disperse to collect resources that can be transported back to the camp. This distinction is often summed up by suggesting that foragers move people to resources, whereas collectors move resources to people (see Fig. 1).

Binford based his forager pattern on the Gwi San and his collector pattern on the Nunamiut, two groups living in very different, though equally extreme, environments. However, these groups were intended to represent ends of a continuum of hunter-gatherer adaptation rather than a dichotomy, and have found parallels in other, related schemes. In particular, Woodburn's (1982) distinction between immediate and delayed return foragers is an independently devised scheme that mirrors Binford's, and in Paleolithic archaeology, the distinction drawn by Lieberman and Shea (1994) between circulating and radiating mobility is based directly on Binford's (1980) work. Of particular relevance to archaeological applications of the collector/forager model is Binford's assertion that collectors will create a series of distinct site types that will

Hunter-Gatherer Settlement and Mobility, Fig. 1 Schematic of Binford's (1980) distinction between foragers and collectors. The figure shows part of a *seasonal round*; note that collectors produce three additional site types during their logistical movements away from the residential base

not be created by forager systems. Both collectors and foragers create *residential bases* – the equivalents to the home bases identified by Lee and De Vore and employed in archaeological reconstructions by Leakey and Isaac. Both also create *locations* – places where particular extractive tasks are carried out, though Binford notes that collector locations may be more visible to the archaeologist than forager locations due to the tendency for logistically organized groups to gather larger amounts of a given resource in a single trip. In addition to residential bases and field camps, collectors create the three additional site types, designated by Binford as *field camps*, *stations*, and *caches*.

A field camp is a temporary base for a group engaged in a logistical foray that keeps them away from the residential base for at least a single night, while a station is a site where a special-purpose task group would locate itself while gathering information on, for example, movements of game. The importance of information about the wider environment to hunter-gatherers is discussed further below. Finally, caches are relatively self-explanatory, being temporary stores of resources located away from the residential base. Note that the structured storing of food is exclusive to collectors and again parallels Woodburn's (1982) notion of a delayed return economy. Binford's (1980) critical insight regarding these site types, as they relate to the microscale mobility continuum from foragers to collectors, is that given locations may serve multiple purposes, being, for example, sequentially field camps, locations, and caches. Given that collectors produce a greater number of generic site types and that the site types a system produces can be combined in potentially any sequence, collectors should be identifiable in the archaeological record via greater intersite variability. Given this signature of a collector system, most archaeological uses of Binford's system have suggested that collectors do not appear until the Upper Paleolithic. In one contradiction to this pattern, Lieberman and Shea (1994) suggested that Neanderthals in the Near East practiced radiating mobility, whereas later modern humans resorted to circulating mobility as a result of climatic deterioration.

Mesoscale Mobility

While microscale mobility describes the way in which a hunter-gatherer group organizes itself to

ensure adequate resources are transported to the residential base, mesoscale mobility involves the movement of that base when resources are depleted. Micro- and mesoscale strategies are closely related since increasing logistical mobility at the microscale will tend to reduce residential mobility at the mesoscale. However, there is a qualitative difference between these two scales of mobility since the latter will involve relocation of the residential base, the main anchor of the group to the territory. The frequency and distance of residential moves will have profound consequences for the maintenance of material culture, with generic least-effort criteria suggesting that investment in site maintenance and structure will be reduced in highly mobile groups. Furthermore, toolkits of highly mobile foragers will either be streamlined, with only the most vital tools carried, or reduced to expedient manufacture, with simple tools made as and when they are needed. It is at the mesoscale that the fundamental assemblage variability of the residential base articulates with the mobility pattern.

As with microscale mobility, the foundational work on mesoscale relocation patterns was by Lewis Binford, in his seminal 1982 paper *The Archaeology of Place*. The fundamental advance of this paper was that it proposed three idealized relocation patterns – the half-radius continuous, complete-radius leapfrog, and point-to-point patterns – that, together with the microscale considerations discussed above, could be used to develop a relatively complete classification of hunter-gatherer mobility. The idealized patterns Binford proposed sought to directly link the quality of an environment (the richness of its resources) to the level and type of mobility practiced by the hunter-gatherers inhabiting it. Figure 2 shows the three patterns Binford (1982) proposed, each of which is briefly explained below. Each of the patterns is based around a simple idea of *economic zonation* around sites, with a nearby foraging zone and a more distant logistical zone which is exploited only partially from each site. The need to relocate is driven primarily by the depletion of resources within the foraging zone; when it is no longer energetically efficient to search for resources within this area or, equivalently, when this area has become so large that transport costs are prohibitive, it is time to move the residential base. The simple geometric theory developed by Binford (1982) suggests that the minimum distance the group should move would be twice the radius of their foraging area, thus ensuring that they do not traverse land from the new base that has been depleted during occupation of the old (see Fig. 2).

The first of Binford's patterns, the half-radius continuous pattern (Fig. 2a), is characteristic of high mobility groups (in the sense that they move the residential base often, rather than far) who do not develop the logistical radius to any great extent. The double-radius leapfrog pattern (Fig. 2b) is in many ways the quintessential expression of the geometric theory, with the size of the current foraging zone determining the distance of the next residential move. Note that while foraging zones, which are exploited intensively, must never overlap, logistical zones frequently do overlap, since they may contain limiting resources (e.g., sources of water or flint) that are non-depleting or recurrent. While the double-radius leapfrog pattern is common among hunter-gatherers in high-quality environments, an alternative known as the point-to-point pattern (see Fig. 2c) is more common in lower-quality habitats. When considered relative to the microscale patterns of mobility discussed above, it is suggested that there is continuum from half-radius continuous forager groups to point-to-point collector groups, though this relationship is anything but rigid. In both the double-radius leapfrog pattern and the point-to-point pattern, residential bases are located in areas that afford access to vital resources such as water, food, and fuel; however, in lower-quality habitats, the confluence of these key resources is rarer, requiring hunter-gatherers to engage in longer residential moves and to prospect beyond the logistical zone for future residential locations.

The geometric pattern of hunter-gatherer mesoscale mobility, as expressed ideally in Binford's complete-radius leapfrog pattern (see Fig. 2b), allows for the delineation of a number of basic hypotheses about the distances hunter-

Hunter-Gatherer Settlement and Mobility, Fig. 2 Three modes of mesoscale mobility, after Binford (1982:10). Dashed arrows represent residential moves; see text for further details and discussion

gatherer groups should move depending on their size, the duration of site occupation, and the quality of the habitat surrounding the site. With all else equal, the foraging zone could be expected to increase with increasing group size, increasing duration of occupation, or with decreasing habitat quality; furthermore, given the relationship between the area and radius of a circle and the

Hunter-Gatherer Settlement and Mobility, Fig. 3 Graph (**a**) shows the relationship between average occupation duration and average move distance as predicted by Binford's complete-radius leapfrog model for three arbitrary levels of habitat quality. Assuming that the average number of moves per year is equal to 365 divided by average occupation duration, graph (**b**) shows the relationship between this variable and average move distance. (After Grove (2009: 224))

requirement that a group should move at least twice the radius of the foraging zone, the form of these relationships can be quite accurately predicted (Grove 2009). Concentrating on mobility-specific variables, the average move distance – the first key index of mobility – can be expected to increase in proportion to the square root of average occupation duration (media object) or group size (or to decrease similarly in proportion to the square root of habitat quality). Similarly, since the average number of moves per year – the second key index of mobility – is simply 365 divided by average occupation duration (in days), we can expect average move distance to decrease in proportion to the reciprocal of Media object (see Fig. 3).

In testing these relationships with a large body of hunter-gatherer data, Grove (2009) found that habitat quality was by far the most important variable in determining mobility patterns, with occupation duration of importance only to groups heavily dependent on meat. This last result is likely due to the increased danger of insect-borne infection created by the buildup of carcass-processing detritus and, in certain environments, the risk of such detritus attracting potentially dangerous scavenging carnivores. Group size was found to have little effect on move distances, though this is in fact because group size variability is mediated in hunter-gatherers by frequency rather than distance of movement. As a generic characterization, larger groups move similar distances but move more frequently than smaller groups. In a detailed examination of data on the Dobe area!Kung collected by Yellen (1977), Grove (2009) was able to show that, at a finer scale, the size of the site (measured as the limit of the main artifact scatter) is determined by group size and occupation duration, the size of the foraging radius by habitat quality, and the size of the logistical radius by the percentage reliance on meat and the extent of logistical mobility. Thus, Binford's (1982) notion of *economic zonation* continues to be of considerable value in studies of hunter-gatherer mobility.

Macroscale Mobility

In addition to the relatively local foraging and logistical zones outlined by Binford and discussed above, hunter-gatherers range over vast areas of land and forge links with distant bands for the purposes of trade, exchange, and what we might loosely call *insurance*. Since the work of Wobst (1974), there has been considerable interest in such long-distance relationships between hunter-gatherer groups, and this interest has frequently extended into archaeological applications. Early ethnographers often sought to classify hunter-

gatherer groups into hierarchically inclusive series, with several families forming a band, several bands forming a clan, and so on up to the level of the tribe. The latter has traditionally been considered to equate to a language boundary; all those who speak a given language (or distinct dialect) belong to a given tribe, to the exclusion of those who speak other languages. This formation of boundaries sets up a situation in which tribes themselves (to the extent that they are genuinely coherent entities) may maintain equitable or hostile relations with neighboring tribes. In fact, hunter-gatherer mobility is for the most part facilitated by relatively equitable bonds, particularly where notions of common descent are reinforced by shared aspects of material culture. It should be noted, however, that before extensive contact with agriculturalists, some hunter-gatherer groups, notably aboriginal Americans, did reach population densities sufficiently high to lead to violent disputes over land and resources.

Archaeologists have examined patterns of prehistoric hunter-gatherer trade through the movement of artifacts, particularly in the Upper Paleolithic of Europe. Gamble (1982) suggested that the wide distribution of particular symbolic artifacts acted as a bonding mechanism such that groups traveling far, at low density, and encountering each other rarely would have some common ground with which to mediate social exchanges. From a different perspective, Vanhaeren and d'Errico (2006) attempted to map ethnolinguistic (i.e., tribal) boundaries in early Upper Paleolithic Europe by examining the areas associated with specific assemblages of bead types. Thus, hunter-gatherer mobility at this macroscale is characterized by a combination of both rigid and permeable boundaries, with archaeologists such as Gamble (1999) suggesting that the evolution of human society has in large part revolved around the establishment of equitable bonds with ever more distant groups, binding local bands into ever more inclusive networks. Records of the transport of artifacts and raw materials studied by several authors have broadly supported this thesis, with materials traveling further and further during the progression of the Paleolithic.

Though trade and exchange are valuable facets of macroscale hunter-gatherer mobility, they may in fact be undertaken merely to lubricate the more enduring, socioecological process of bond maintenance for *insurance* purposes. Binford has suggested that beyond the logistical zone is a much larger and more thinly exploited zone referred to among the Nunamiut as the *visiting* zone. Behavioral ecologists are beginning to realize that information about the surrounding habitat – including, crucially, the locations of conspecific groups within that habitat – is a vital currency for all animals. Among humans this need for knowledge is paramount and is reflected in the establishment of information-gathering *stations* among logistically organized groups. One undeniable difference between modern hunter-gatherers and other primates (and presumably, many of our hominin ancestors) is the tendency to transport food and other resources rather than relying on a feed-as-you-go subsistence pattern. Highly logistical collecting patterns are the antithesis of the generic primate pattern, but they rely on securing a great deal of intelligence about an ever larger area of habitat, and, with the risk of subsistence failure an ever-present concern, they rely also upon the need to develop equitable bonds with neighboring groups.

Whallon (2006) has argued that a vital purpose of long-distance mobility among modern hunter-gatherers is the establishment and maintenance of extended social networks that not only provide information about surrounding habitats but also act as *safety nets* in times of local resource scarcity. Whallon terms this *nonutilitarian mobility*, in recognition of the fact that it has an immediate energetic cost but may have a benefit only in times of crisis; such *insurance* may rarely be used, but if needed, it could be the difference between starvation and survival. Whallon (2006) makes a series of predictions about the value of nonutilitarian mobility to hunter-gatherers in specific situations which follow logically from ecological theory (Fig. 4). The boundary points can be summed up by noting that hunter-gatherer bands have most to gain from establishing equitable bonds with bands from adjacent regions when the correlation of resource availability *between* regions is low and

Hunter-Gatherer Settlement and Mobility, Fig. 4 Expected patterns of *nonutilitarian* mobility among hunter-gatherers in relation to synchrony of resource fluctuation between regions and predictability of resource fluctuations within regions. (Modified from Whallon (2006: 264))

resource availability *within* regions is unpredictable; on the contrary, when resources within a region are predictable or fluctuations in neighboring regions are in synchrony, there is little to gain from *nonutilitarian mobility* directed towards adjacent regions. Put simply, if the nascent region is highly predictable, there is little need to rely on distant neighbors, and if those neighbors experience temporally synchronous periods of resource stress, there will be little chance that they can help. In the latter case, hunter-gatherers may be forced to establish bonds with groups that are sufficiently distant to ensure asynchrony in resource fluctuations.

Harnessing Resources

As well as the three scales of mobility discussed above, a number of general findings that relate hunter-gatherer mobility to specific axes of regional ecology have been reported. Hunter-gatherers have often been divided into classes based on the extent of their mobility; for example, Murdock (1967) distinguishes between fully nomadic, seminomadic, semisedentary, and fully sedentary groups. Using a measure of *effective temperature* to classify environments into different types by habitat, Binford (1980) was able to show that hunter-gatherers in tropical forests and the extreme arctic tend to be highly mobile. By contrast, in temperate forests and deserts hunter-gatherers are spatially constrained by seasonally limiting resources (in particular water) and are therefore forced to rely on food storage as a substitute for mobility. This reliance on a particular limiting resource in a particular location has been referred to as *tethered nomadism* (Taylor 1972), with Kelly (1995) suggesting that most contemporary hunter-gatherers follow this pattern.

A further complex of ecologically based findings relevant to mobility, and with applications of particular importance to the archaeological record, revolves around the relationship between the position of hunter-gatherers within the *trophic pyramid* and its interaction with latitudinal gradients in productivity. The trophic pyramid, an idea due originally to ecologist Charles Elton, describes the fact that primary biomass (essentially plants; level 1 of the pyramid) is assimilated by herbivores (level 2), some of which are in turn predated upon by carnivores (level 3). Due to various factors, some energy is

lost at each level, meaning that there will be lower biomass at each higher level. For example, the weight of all the herbivores in a given area will be substantially less than the weight of all the plants in that area, but substantially more than the weight of all the carnivores in that area. Seen in terms of foraging, this relationship implies that carnivores must travel further to secure the requisite amount of food and that, consequently, they must live at lower real densities.

Although all humans are omnivores, one basic relationship that follows from the logic outlined above is that hunter-gatherer groups reliant on extensive hunting (i.e., those towards the top of the trophic pyramid) will need to cover larger territories in order to fulfill their energetic requirements (Kelly 1995). The problem with hunting is that it is a risky strategy; there is a substantial probability that on any given day, any given hunter will fail to make a kill. The element of risk leads not only to a focus on the sharing of hunted foods but also to a heavy reliance on low-risk plant foods to supplement hunted foods whenever possible. At low latitudes, most hunter-gatherers derive the vast majority of their calorific intake from low-risk, gathered plant foods. However, at higher latitudes, where effective temperatures are lower, edible plant foods are less available, with the knock-on effect that herbivores tend to be larger and more dispersed (Grove 2010). Thus, at higher latitudes, hunter-gatherers are forced to rely on greater proportions of meat and are simultaneously forced to cover much larger territories due to the low densities of their prey. This latitudinal relationship would have had profound effects on the mobility patterns and population dynamics of Paleolithic hunter-gatherers emerging from sub-Saharan Africa to colonize higher latitudes.

Given the latitudinal gradient in subsistence practices and its relationship to mobility patterns, it seems remarkable that hunter-gatherers today can exist in such extreme environments as, for example, north-western Alaska or the Siberian steppe. Whether these environments are suggestive of prehistoric hunter-gatherer adaptations in general is discussed further below, but one thing they do highlight is the possibility of specialization on particular kinds of food resources to lessen the burden of high mobility. Two types of prey provide consistent exceptions to the positive correlation between high latitude and high mobility among hunter-gatherers: migratory ungulates and aquatic resources. In the case of migratory animals such as reindeer, mass kills at natural *topographical funnels* such as river crossings or mountain passes, followed by storage of substantial quantities of the acquired meat, can mediate the need for high mobility for at least part of the year. Aquatic resources can be profitably harvested from a small number of localities, provided the area of water accessible to those localities is sufficiently large; unlike the case with hunting, catching fish in one place today does not reduce the probability of catching fish in that place tomorrow. In both these cases, hunters are effectively shifting the burden of high mobility onto their prey. Both Kelly (1983, 1995) and Grove (2010), using different datasets, have shown that groups reliant on a large proportion aquatic resources are far less mobile than groups heavily reliant on hunting at similar latitudes.

Current Debates

A debate persists in hunter-gatherer studies about the extent to which modern hunter-gatherers are suitable models for the humans of the Paleolithic. Of course the outcome of this debate does not affect the value of studying hunter-gatherers simply to learn more about them, but the fact remains that a lot of the research performed on hunter-gatherer datasets is designed to shed light, via archaeological studies, on our prehistoric ancestors. The lasting critique of Wobst (1978) has largely set the agenda for this debate, laying stress on the fact that surviving hunter-gatherer societies tend to exist only in areas that are not suitable for agriculture, and may therefore be quite dislocated from their traditional habitats. Furthermore, this process of isolation in *marginal habitats* leads to an ignorance of the spatially extensive structures that must once have characterized hunter-gatherer society, with Wobst suggesting that such ignorance is compatible with the (equally dubious) focus in

archaeology on the site as the unit of analysis. Effectively, the encroachment of agriculturalists has led to a disproportionate bias against the recovery of information on macroscale mobility patterns.

Wobst's (1978) observations are particularly germane given the increasing understanding that humans are quite unique in the scale of their social relations and that this expansion beyond the social scales experienced by our primate relatives may have come relatively late in human evolution (Gamble 1999). The study of primate groups has provided an interesting counterpoint to studies of modern humans, with many of the basic microscale structures found to be similar in hunter-gatherers, agriculturalists, and certain nonhuman primate species. In particular, the hierarchically nested groupings (with several families forming a band, several bands forming a clan, and so on) described by the likes of Murdock (1967) occur in a number of primate species, with more fluid patterns of aggregation and dispersion being relatively common, particularly among the great apes. The debate concerning which group or combination of groups (and, crucially, from which environmental setting) provide the best models for reconstructions of various periods in human evolution will doubtless continue alongside the hunter-gatherer studies of the future.

Future Directions

Hunter-gatherer mobility is a vitally important subject and will continue to be so, not least because mobility is to many researchers the fundamental characteristic of hunter-gatherers. Following the critique of Wobst (1978), archaeologists have attempted to reconstruct prehistoric mobility patterns from site distributions and have hypothesized about the evolution of trade and exchange in prehistory. Yet without hunter-gatherer data to ground such hypotheses, they remain essentially untested. Substantial collections of data on hunter-gatherer mobility patterns have been assembled, notably by Murdock (1967) and Binford (2001), and these remain as powerful resources for model building and generalization. The greatest challenge remains to accurately reconstruct the extent of precontact social interaction; evidence of this remains not only in the current macroscale mobility patterns but also in the evidence of oral testimony and folklore. The application of modern quantitative techniques such as network analysis to data on mobility, trade, and exchange should produce substantive insights into hunter-gatherer society, both prehistoric and modern.

Hunter-Gatherer Subsistence Variation and Intensification

Introduction

Approaches to hunter-gatherer subsistence have progressed significantly in recent decades. Stereotyped views of hunter-gatherers as simple, even backward representatives of an early stage of human social evolution have given way to more nuanced ones that reflect a growing recognition of the tremendous variation among hunter-gatherer groups (Kelly 2007). Since the 1960s, studies of hunter-gatherer subsistence have increasingly broadened their focus from men's role as hunters and sole providers, acknowledging the importance of plant foods, fish and shellfish, and women's contributions to the diet (Kelly 2007: 65). The 1966 "Man the Hunter" conference in Chicago, organized by Richard Lee and Irven DeVore, was pivotal in this regard, demonstrating empirically – and in stark contrast to all previous work on the subject – that hunter-gatherers were no less "affluent" than agricultural and pastoral societies (Finlayson 2012) and that gathering provided a substantial portion of the diet. The years since "Man the Hunter" have also seen a shift from preoccupation with social evolutionary stages and descriptive cultural histories toward identification and explanation of the processes that account for variation within and between hunter-gatherer societies, often approaching social organization and subsistence technologies from an ecological or evolutionary perspective. Postprocessual and revisionist scholars have contributed to our understanding of hunter-gatherer subsistence greater awareness of the social, historical, and symbolic aspects of diet and human–animal interactions and have advocated for increased contributions by and collaborations with indigenous groups. Feasting events, food sharing and storage, prestige foods, tabooed animals, circumscription, costly signaling, transmission of knowledge, trade, globalization, identity, individual agency, landscape use, and power and dominance are among the topics addressed from this diversity of perspectives using hunter-gatherer subsistence data.

Definition

Simply put, *subsistence* refers to the ways people meet their basic needs, particularly the procurement and processing of food. In practice, though, subsistence is tied to local ecologies, technology, sociopolitical organization, and connections to external groups, for example, and so has implications well beyond sustenance. Addressing such complex subsistence-related topics as gender division of labor and emergent inequality requires a

clear presentation of related definitions, theoretical concepts, and methodological approaches to hunter-gatherer subsistence.

Key Definitions for Hunter-Gatherer Subsistence Studies

Hunter-gatherers are defined in various ways, most often in terms of their subsistence economy, social organization, or ideology (Jordan 2009: 448). Here, we define hunter-gatherers as those people whose subsistence economies are based on wild (i.e., undomesticated) plants and animals (but see "Key Issues/Current Debates," below). Prior to approximately 12,000 BP, the entire human population relied on some form of hunting and gathering. Meta-analyses of hunter-gatherer subsistence variation indicate strong correlations between environment and diet and attempt to quantify them using measures of primary production (PP) and effective temperature (ET) (see "Explaining Variation," below) (Kelly 2007: 66–71). For example, in high-latitude regions such as the Arctic, where PP is low and much of the plant biomass inedible for humans, local human groups tend to rely heavily on meat. Conversely, in equatorial and lower latitude environments including tropical forests and temperate deserts, PP is higher and more of it is available to humans, resulting in generally greater reliance on plants. Aquatic resources are more often staples in colder climates such as coastal areas in northern latitudes than at lower latitudes even if they are similarly accessible (Kelly 2007: 71).

Anthropologists have used a variety of concepts to further categorize subsistence variability among hunter-gatherers. Woodburn (1980) distinguishes between immediate- and delayed-return hunter-gatherers on the basis of their consumption patterns. Immediate-return hunter-gatherers consume food shortly after they acquire it and rarely depend on any form of storage. Delayed-return hunter-gatherers typically live in seasonally variable environments and rely on storage technologies to survive the season(s) of low resource availability. Similarly, Lewis Binford's (1980) definition of *foragers* and *collectors* identified relative dependence on storage, combined with kind and degree of mobility, as a key distinction between hunter-gatherer groups. Foragers "move consumers to food," so to speak, exploiting the resources within a reasonable radius around a base camp until depleted and then moving the entire group to the next such location. Conversely, collectors tend to establish base camps in places with access to a variety of resources, perhaps located farther from camp than in the previous scenario, and rely on "task groups" to move food resources to consumers in a sometimes extensive system of logistical mobility. Some authors consider forager-like hunter-gatherers *resource diversified* and collector-like hunter-gatherers *specialized* (Chatters 1987), since the former are search oriented and take a wide range of resources on encounter while the latter deliberately pursue particular species.

Resource intensification is an important concept in hunter-gatherer subsistence studies. Boserup (1965) defined intensification as a process of extracting more energy (e.g., kilocalories) per unit of land in response to population growth and increasing resource competition. For Boserup, an economist interested in agricultural development, this equates to increased cropping frequency and use of multi-cropping tactics. Applied to hunter-gatherers, Boserup's intensification model predicts expanding diet breadth to include lower-ranked resources, such as small mammals or seeds. In both applications, intensification *increases* total productivity, but *decreases* productive efficiency, since it requires more intensive labor per unit energy extracted.

Optimal foraging models, initially developed in sociobiology and reframed by human behavioral ecologists to study human foraging behaviors, are an increasingly common tool for identification and explanation of resource intensification in the archaeological record (Kelly 2007). The "fine-grained prey" or "diet breadth" model is particularly useful for understanding resource intensification. In this model, resources are ranked according to their post-encounter energetic return rates (energy gained relative to energy expended in handling) and taken on encounter if they are a member of the optimal set – those resources that produce the optimal rate of energetic return (greatest energy per unit time). Diets broaden to

include lower-ranked resources when search costs for higher-ranked ones are high (i.e., they become scarce relative to human foragers). Broughton et al. (2011) showed recently that prey body size and return rate are strongly positively correlated, legitimating the common practice of using body size as a proxy for resource rank. Thus, an increase in small mammals or seeds – ostensibly low-ranked resources – in an archaeological record is often interpreted as evidence of decreased foraging efficiency. More specifically, an archaeological shift from reliance on hunting to plant-based subsistence is usefully viewed in light of Boserup's and more recent discussions of intensification. The intensification process has also been productively studied in reference to technological change that rearranges rankings of prey species. The best examples of this are associated with the evolution of Mesolithic fishing and grain harvesting and Northwest Coast maritime adaptations (Hayden 1981).

Archaeological Analyses of Subsistence

Subsistence practices can be interpreted through a variety of archaeological materials. For example, zooarchaeologists analyze animal remains recovered from archaeological deposits, identifying bones, teeth, shell, and other faunal materials to skeletal element and taxon. Cataloging the kinds and quantities of different skeletal parts and taxa, zooarchaeologists can address a variety of subsistence-related questions including dietary breadth and the relative importance of particular taxa, seasonal use of resources, gender division of labor, feasting behavior, trade (e.g., foraged resources exchanged for cultivated ones), and resource intensification, as well as changes in these behaviors through time.

In recent decades, paleoethnobotany has emerged as a vibrant field of study, able to address many of the same questions mentioned above and extending beyond them to include specific interactions between people and plants, environmental catalysts for dietary change, medicinal practices, plant resource domestication, and the transition to food production. Macrobotanicals, such as charred seeds and plant parts collected using the flotation method, and microbotanicals such as pollen and phytoliths, extracted from soil samples chemically or through ashing, are identified to taxon and their relative frequencies used to interpret prehistoric subsistence behaviors.

Both zooarchaeology and paleoethnobotany are aided by the relatively new and growing field of archaeochemistry, which produces valuable data previously unavailable through traditional archaeological methods. Archaeochemists extract anthropogenic residues from soils, coprolites, lithic tools, ceramics, and fire-cracked rock to reconstruct prehistoric diets and environments.

Conventional methods of addressing hunter-gatherer subsistence remain important as well. The spatial and temporal distributions, relative frequencies and kinds of projectile points, ceramics, basketry, storage features, and diagnostic site types, combined with ethnographic and ethnoarchaeological interpretations, form the foundation of many subsistence studies.

Historical Background

Enlightenment notions of progress and misinterpretations of Darwinian concepts, which at the time were still very new to science, led progressive social evolutionary theorists of the late nineteenth century to describe hunter-gatherers as modern representatives of a primitive human condition – the lowest rung on the human evolutionary ladder, at the top of which was nineteenth-century industrial Europe. Evident in the writings of Lewis Henry Morgan and E.B. Tyler, for example, is the resultant tendency to ignore variation in hunter-gatherer subsistence practices; treating, for example, all hunter-gatherers, living and prehistoric, as if they were cut from the same cloth. Viewed as socially backward and intellectually inferior, hunter-gatherers were pitied: Unable to achieve agriculture and its attendant social advances, hunter-gatherers' existence was characterized by "continual fear and starvation, a perpetual and barely adequate search for food" (Kelly 2007: 16). Subsistence differences between groups, when entertained at all, were attributed to contacted with more "civilized" neighbors.

At the turn of the twentieth century, ethnographer Franz Boas rejected the progressive social evolutionary notion of parallel evolutionism. He cultivated the opposing school of historical particularism – based on the idea that cultural traits including hunting and gathering are the product of groups' unique histories rather than of stages in an inevitable, stepwise evolutionary progression – and generated a large and prolific group of graduate students. Two such students, however, Clark Wissler and Alfred Kroeber, observed that, despite their particular histories, certain culture traits tended to cluster geographically, coincident with major food resources (i.e., bison in the Plains, salmon in the Northwest, and wild seeds in the Great Basin) (Kelly 2007: 40).

It may have been this vaguely ecological description of "culture areas" that led Julian Steward, a student of Kroeber's, to explore the relationship between society, technology, and environment, an approach he dubbed "cultural ecology" (1969). Steward took a comparative approach to the ways societies extracted energy from their environments. He believed that the interaction between technology and environment determined subsistence behavior and that, while common environments might lead to common subsistence behaviors, technology, as a product of groups' particular histories, made for important differences.

Lewis Binford and other "new archaeologists" of the 1960s were likewise interested in environmental explanations of hunter-gatherer subsistence. Binford in particular argued that all behavior was governed by lawlike principles that could be understood through scientifically rigorous methods, and many of his explanations of cultural change observed in the archaeological record were tied to evidence of environmental change.

While many of these interpretations were eventually rejected as environmentally deterministic, the new archaeologists – also referred to as processualists – spawned a distinct area of study, the focus of which was interpreting dynamic human behaviors (especially subsistence behaviors) from the static archaeological record. This "middle range" body of theory included studies of taphonomy, which are now a crucial means of distinguishing human from natural influences on the archaeological record of subsistence behaviors. It was also at this time that ethnoarchaeology became a mainstay of middle range research, applying ethnographic methods specifically to the study of behaviors that leave material residues (e.g., butchery and discard). For example, Binford's own observations of Nunamiut butchering gave archaeologists a "frame of reference" for interpreting patterned faunal remains.

In applications not entirely dissimilar to middle range theory in their attempt to reconstruct behaviors from patterns in the archaeological record, anthropologists of the 1980s and 1990s began to adopt models developed in sociobiology, establishing a new explanatory framework for the study of humans known as human behavioral ecology (HBE). Human behavioral ecologists use mathematical and conceptaul models to explore human decision-making in terms of particular currencies (e.g., kilocalories) and constraints (e.g., resource availability). Optimization models including diet breadth, patch choice, and central place foraging reduce complex human behaviors to a tractable number of variables, providing testable predictions that sometimes lead to surprising insights to human subsistence behaviors.

Optimal foraging models have also been at the forefront of intensification studies. Research of this kind got its start in California where archaeologists hypothesized that resource depression occurred during the precontact period prior to c. 1000 BP due to high population densities and competition for resources. It was not until populations declined due to drought during the Medieval Warm Period (c. 1000–1300 BP) that key resources rebounded. By the time Spanish explorers reached the central coast of California some 200 years later, the region seemed to be teeming with high-ranked game. This perception of precontact California persisted even among archaeologists until researchers including Terry Jones and William Hildebrandt used faunal evidence to challenge it, demonstrating there was indeed depression of high-ranked sea lions and fur seals and intensive use of more evasive harbor seals and sea otters. Jack Broughton also found

evidence of depression and intensification of resources in the San Francisco Bay during the late Holocene evidenced through decrease of large sturgeon and increase of low-ranked fishes through time.

Postprocessual and revisionist scholars reject the idea embraced by new archaeologists and human behavioral ecologists that cultures evolved simply as a way to adapt to the surrounding environment and that there are lawlike mechanisms governing human behaviors. Postprocessualists argue that intra-community dynamics tied to politics, socioeconomics, and ideology are also important variables that shape societies; cultural evolution is historically contingent. From this perspective, subsistence studies must go beyond strictly materialist, ecological, or environmental influences, to consider such things as social stratification and unequal access to resources within communities, feasting and other rituals tied to food, and food symbolism.

Key Issues/Current Debates

Hunter-Gatherer Subsistence Variation

Use of Ethnographic Data

Ethnographic and ethnoarchaeological methods have improved dramatically since the pioneering work of Franz Boas and his students, sometimes incorporating sophisticated technologies and techniques designed to capture invisible or elusive – but critical – aspects of foraging behavior. For example, Pacheco-Cobos et al. (2010) use global positioning systems and biotelemetry to track foraging pathways, energy expenditure, and overall foraging efficiency among men and women of an indigenous Mexican community. Yet even modern studies may fail to accurately characterize subsistence regimes; time-limited observations can mask important variation in daily, seasonal, and supra-annual foraging goals and decisions, for instance. When incorporated into broader comparative studies, mischaracterizations can obscure causes of subsistence variation.

Technology and technique may continue to close gaps in our knowledge of hunter-gatherer subsistence, or they may be outpaced by ethnographic subjects' adoption of "nontraditional" tools and practices, which, some might argue, would make them "inauthentic," inappropriate models of past behaviors. This may be a slippery slope, however, since it is clear that even relatively recent prehistoric innovations – including the bow and arrow – fundamentally changed foraging practices. Moreover, even some apparently "pristine" ethnographic hunter-gatherers (e.g., Kalahari Bushmen) shifted subsistence foci – from hunting and gathering to farming or herding and back again – several times in the past (Ames 2004), leaving students of subsistence variation caught between the impropriety of strict reliance on ethnographic data and an archaeological record that is often woefully incomplete. Yet, "there is no alternative to using our knowledge of modern peoples to help us penetrate the past" (Ames 2004: 366); success requires a body of theory equipped to manage the respective shortcomings of both records (see "Explaining Variation," below).

Defining "Hunter-Gatherer"

Some amount of reported subsistence variation is semantic. Definitions of "hunter-gatherer," for example, differ in their tolerance of 'inauthentic' behaviors, including market participation or trade for agricultural products, the tending of small gardens, or keeping of wild animals for milk or eggs, even whether a group engaged in these activities at some time in the past (see above; Ames 2004). What is more, some studies define "hunter-gatherer" in terms of social organization rather than subsistence economics, classifying variation along social dimensions such as group size and flexibility of membership, power structure, and the distribution of wealth.

Hunter-gatherers, however they may be defined, are often further distinguished based on the relative importance of particular foraging strategies (e.g., hunting versus gathering) or contributions of major food classes (e.g., terrestrial game, fish). Currently, there are no standards for these subdivisions, and dietary contributions, for

example, are as often reported in terms of net weight as in kilocalories, if they are quantified at all. Moreover, economic relationships with other groups can artificially inflate the importance of hunting, for example, if some portion of hunted resources is traded for carbohydrates (Kelly 2007).

Consensus among anthropologists may be untenable. Still, while explaining hunter-gatherer subsistence variation does require coherent classifications, internal consistency may be sufficient, and some bodies of theory are no less fruitful for their deliberate agnosticism toward prescriptive categories.

Explaining Variation

Two primary schools of thought approach hunter-gatherer subsistence variation in fundamentally different ways. Historicists focus on groups' particular histories, viewing subsistence in a socio-cultural context, with the aim of documenting variation and describing its historical origins. Conversely, materialists often take a comparative approach, viewing subsistence in an ecological or evolutionary context, with the goal of distilling and explaining subsistence differences. These perspectives produce very different assessments of hunter-gatherer subsistence variation.

The historical approach is fine-grained and particularistic, accounting for exceptional cases that do not fit materialist generalizations about subsistence and environment. However, particularistic studies also "maximize heterogeneity and mask similarities" between groups and, ultimately, lack explanatory power (Ames 2004: 370). While some historicists claim that the alternative, materialist perspective is callously reductionist and environmentally deterministic in its drive to explain variation, this is not necessarily so.

Materialists start from the premise that the global history of subsistence similarities is unlikely to be purely coincidental. Within the materialist school, however, there are various approaches to explaining these similarities, including ones that are, in essence, environmentally deterministic (though few anthropologists would self-identify as such). Leaving aside definitional inconsistencies, hunter-gatherer diets have reliably been shown to correlate with environmental variables. Effective temperature (ET) – an estimate of regional seasonality and productivity derived from the mean temperatures of the warmest and coldest months of the year – and primary productivity (PP) – net annual above-ground plant biomass – seem to account for much of the variation in subsistence foci (e.g., percent reliance on hunting; Binford 1980; Kelly 2007) and have been interpreted as the primary explanation for that variation. However, simply recognizing patterns and identifying important environmental variables falls short of explanation, particularly since strong correlations sometimes emerge only after a number of outlier groups are removed. It is also true that ET and PP are much better predictors of groups' reliance on plants than on animals (Kelly 2007) and that, alone, they simply cannot predict which of all available food items in an environment are exploited, when, how, and by whom, the important intercultural differences masked by the approach.

Human behavioral ecology capitalizes on documented patterns of diet–environment co-occurrence and attempts to address the very subtleties that a purely environmental approach cannot. Despite its strongly cohesive Darwinian paradigm, HBE permits considerable range in subsistence models. Historically, optimal foraging models have dealt in kilocalories, but the last 10 years have seen the inclusion of alternative currencies including nutrient complementarity and prestige. Recognition that hunter-gatherers may be hunting (or gathering) for social reasons rather than strictly for sustenance has led to both innovative research and heated debates.

Other areas currently generating interesting research are within-group specialization, particularly sexual division of labor; how an individual forager's diet breadth can change over the course of a single foraging bout and what effect this might have on long-term, material records of foraging; and the effects of cultural transmission on cross-cultural variation in tools, foraging techniques, and dietary composition, all of which are key to understanding subsistence variation.

Critics have argued that HBE models, designed to predict individuals' behaviors, may not be appropriate for archaeological analyses, which most often deal in population-level data, generated over long time spans and muddied by taphonomy. Models are deliberate simplifications of complex relationships between people and resources, and if the archaeological record represents "average" behaviors, HBE models can still be used to test hypotheses of prehistoric foraging. Ripe for development are models that predict the effects of group hunting, sharing, and tolerated theft on the material record and the range of subsistence behaviors not evident in the ethnographic record.

Intensification

Study of the process of intensification is primarily the province of archaeologists and historians. Unfortunately, intensification – particularly incipient intensification (e.g., flood irrigation, fertilization, swiddening) – is not always clear in the archaeological record. Even quantifiable aspects of dietary change, such as isotopic signals of increasing cultigen consumption, can be controversial since in situ intensification cannot always be distinguished from trade.

Though sometimes materially ambiguous, intensification is theoretically tractable in light of HBE: foragers should invest in activities that increase productivity per unit area when doing so improves overall subsistence returns. Importantly, foraging theory predicts that people may stop intensifying, perhaps returning to a previous state of unintensified hunting and gathering, if the initial pressure to intensify is relaxed. While HBE provides an explanation for intensification, it invites exciting research on proximate causes (e.g., environmental change, circumscription, *perceived* resource scarcity, technological adaptations) that will have important historical and cultural components.

International Perspectives

Subsistence studies remain at the forefront of hunter-gatherer research throughout the globe. In Australia, subsistence research utilizes optimal foraging theory to address adaptations to desert environments and resource intensification among Aboriginal communities during the late precontact and contemporary periods. Bird and Bleige Bird (e.g., 2005) use OFT to address food sharing, use of fire to improve foraging yields, and differential hunting strategies among men, women, and children. On a broader scale, O'Connell and Allen (2012) consider demographic pressure, climatic instability, and depletion of high-ranked resources as potential causal factors for the initial colonization of Sahul (Australia and New Guinea) by populations that traveled from the Asian mainland and through Wallacea c. 44,000–46,000 years BP.

Since the 1960s, hunter-gatherer research in Africa has generated both cutting-edge data and considerable controversy. Richard Lee's work among the Kalahari Bushmen challenged the long-held progressive social evolutionary notion that hunter-gatherers were forever toiling to eke out a living, while agriculturalists, through food production and relative independence from the whims of the environment, freed themselves to engage in intellectual pursuits. The!Kung data suggested instead that hunter-gatherers spend far less time in food procurement than agriculturalists, even making them the "original affluent society" (Jordan 2009). Further controversy was generated in the 1990s when a group of "revisionist" anthropologists argued that the Kalahari Bushmen were inappropriate models of a "pristine" hunter-gatherer lifeway given their long and complex history of interactions with neighboring agropastoralists and European colonists (Wilmsen 1989; see also "Key Issues/Current Debates," above). Like Lee's work during the 1960s, modern studies among African hunter-gatherers are on the cutting edge of subsistence research, incorporating research designed to probe more deeply into foraging costs and returns and food sharing, for example (Mitchell 2002).

Subsistence has been a primary focus of Americanist hunter-gatherer research for many decades, and the range of subsistence questions addressed is truly impressive. As one of the last major colonization events, the peopling of the New World has been an active area of study since the

discipline's beginnings and so has generated a large body of theory and data, much of which is subsistence based. The so-called Clovis-first hypothesis indicates that small groups of hunter-gatherers followed herds of Pleistocene megafauna (e.g., mammoths) across the Bering Land Bridge to the New World, perpetuating the stereotype that hunter-gatherers subsist primarily on meat procured by men. However, more recent research suggests not only that people may have colonized the New World via the coast, and so would have diets that included marine resources, but also that even fully "terrestrial" Paleoindians had rather broad diets. Indeed, the earliest widely accepted site in the New World, Monte Verde in Chile, shows extensive use of large and small animals, terrestrial plants and seeds, and seaweed. As more early sites like Monte Verde and the Gault site in Texas yield convincing evidence of very broad Paleoindian diets, our understanding of early Americans' subsistence behaviors will be refined. Many South Americanists also remain committed to understanding subsistence variability in relation to ethnic group identity (e.g., Cornejo & Sanduezar 2011).

Domestication of plants and animals has dominated subsistence research in the Near East at least since the 1960s. Recent investigations provide morphological evidence for plant domestication by 10,500 cal BP, and evidence for active management of wild plants and animals predates domestication by a 1000 years or more (Zeder 2011). New data indicate that domestication of plants and animals occurred simultaneously in different areas throughout the Near East rather than originating solely in the southern Levant. For example, domesticated einkorn, emmer, and pulses, as well as sheep, pigs, cattle, and potentially goats, appear to have originated in the central Fertile Crescent, near the upper portions of the Tigris and Euphrates Rivers (Zeder 2011: 230). It is now clear that human groups in the Near East combined hunting and gathering, cultivation of domesticates, and management of wild crops and animals for approximately 4000 years before developing subsistence economies based mainly on domesticated crops and animals.

Notable research in Eurasia investigates anatomically modern *Homo sapiens* and *Homo neanderthalensis* adaptations during the Pleistocene (Stiner & Kuhn 2006). Data imply that subsistence behaviors changed little during 200,000 years of the Middle Pleistocene; large-bodied prey species, as well as animals susceptible to over-predation, such tortoises, were hunted consistently. Nonetheless, hunting pressure appears not to have influenced prey population densities (i.e., animal frequencies do not change in the archaeological record) because *H. sapiens* and *H. neanderthalensis* populations were insufficiently large. During the transition to the Upper Paleolithic, however, there appear to have been localized depressions in both large and smaller mammal populations, perhaps due to increased human populations and overhunting. Another significant area of Eurasian subsistence research has concerned adaptations to high-latitude environments. Russian scholars have offered important insights into the world's earliest arctic adaptations. For example, the Yana RHS site in Siberia, which dates to c. 27,000 BP, demonstrates that people were adapted to high Arctic environments much earlier than previously assumed, with diets that included mammoths, horse, reindeer, bison, and hare (Pitul'ko et al. 2004).

Future Directions

Several lines of research will continue to move us beyond simple description and reductionism toward an ever more holistic understanding of hunter-gatherer subsistence variation. Continued development of technologies designed to track concealed aspects of the foraging calculus (e.g., energy expenditure, nutrient complementarity) will hone quantifications of relevant costs and benefits. Behavioral models of subsistence will be improved by incorporation of these data as well as by persistent attention to potential alternative currencies and constraints. Emergent

research on cultural and historical learning biases that help shape hunting technologies, approaches to storage and methods for improving nutrient bioavailability, for example, will surely help to explain subsistence variation among hunter-gatherers living in similar environments. Command of models that incorporate learning biases will be enhanced by attention to the findings of behavioral research laboratories that use game theory to understand strategic decision-making and to those in psychology and cognitive neuroscience aimed at understanding human perceptions and motivations.

Common to all of these research endeavors is the integration of historicist and materialist perspectives; it is clear that both are necessary to explain subsistence variation. Although archaeological applications are still few and fairly simple, there is a growing recognition that cultural transmission theory (CT) offers a principled means of uniting the two approaches. Like HBE, CT deals in mathematical models, formalizing the effects of culture and history (e.g., technology and subsistence practices) on the adaptive equation, but CT has the advantage of being able to connect individual behaviors with population outcomes by looking at different spatial and temporal scales. A truly modern approach to hunter-gatherer subsistence will incorporate both social and environmental variables to understand cross-cultural variability in foraging tools and practices, food preferences, labor specialization, and long-term subsistence change.

Hunter-Gatherers, Archaeology of

Anna Marie Prentiss
Department of Anthropology, The University of Montana, Missoula, MT, USA

Introduction

The study of hunter-gatherer societies remains fundamental to archaeological research around the globe. Hunting and gathering societies have existed in virtually every environment from the extreme (e.g., arctic, subarctic, subantarctic, alpine, and desert) to the more benign (e.g., temperate interior forests and coasts). Hunting and gathering as an economic strategy dominates human history, given the relatively recent development and expansion of domesticated food production systems. Indeed a number of the world's regions (e.g., North American and Eurasian Arctic and Subarctic, Australia, Tasmania, Patagonia) were peopled by hunter-gatherers until colonization by European groups in the most recent centuries. Archaeologists engage in hunter-gatherer research to address many topics including human evolution, population movements and peopling events, ecological adaptation, forager-farmer interactions, social change, indigenous history, and socio-ideological landscape structure. The archaeology of hunter-gatherers is a dynamic field of study as exemplified by a wide range of

research agendas and debates among its major practitioners. This entry draws from recent works summarizing the current state of the art in hunter-gatherer archaeology (Bettinger 1991; Kelly 1995; Lee and Daly 1999; Binford 2001; Panter-Brick et al. 2001; Barnard 2004; Jordan 2008; Sassaman and Holly 2011) to outline current definitions of hunter-gatherers, historical perspectives, critical debates, international views, and future directions.

Definition

Hunter-gatherers are recognized as a highly diverse set of societies occupying every continent with the exception of Antarctica. However, scholars have struggled over a proper definition for hunter-gatherer. A common view is that hunter-gatherers represent the original human society. Social Darwinists viewed hunter-gatherers effectively as the basal rungs on a ladder of cultural progress (Bettinger 1991). The definition of hunter-gatherer as original human society was evident in neoevolutionary frameworks (e.g., egalitarian band), and later, "pristinist" views asserting some hunter-gatherer groups such as the Ju/'hoansi are in effect survivors from the Paleolithic (Kelly 1995).

A common approach has been to couch definitions in ecological terms primarily in reference to food. Discussions at the "Man the Hunter" conference in 1966 led to a portrayal of hunter-gatherers as people surviving on foods acquired from their surrounding environment. Subsequent research demonstrated that hunter-gatherers employ a diverse array of strategies to acquire, process, and consume those resources. Some hunter-gatherers move groups to food sources, acquire and consume the food, and then move on. In contrast, other hunter-gatherers send task groups from more stable home bases to acquire large quantities of food to be stored and consumed later. Recognition of these differences led to new types, known to James Woodburn as immediate and delayed return hunter-gatherers and Lewis Binford as foragers and collectors (Kelly 1995).

Scholars have also defined hunter-gatherers in sociopolitical terms, typically classifying them as people who live in small, egalitarian social units, typically families or "family bands," lacking formal defended territories, and maintaining flexible residential group membership (Lee and DeVore 1968). Marxian scholars identified a "hunter-gatherer mode of production" whereby hunting and gathering was merely the "glue" holding together the wider package of characteristics (Lee 1988; Panter-Brick et al. 2001). Archaeologists also recognized significant diversity in social organization among hunter-gatherers, leading to an additional typological distinction between generalized and complex hunter-gatherers (Price and Brown 1985).

Typological approaches have been critiqued on a number of grounds. Definitions emphasizing predation of non-domesticated food resources or lack of genetic manipulation of prey populations have not always held up well in the face of realities lived by many societies identified as hunter-gatherer. Some hunter-gatherers rely on nearby agriculturalists for some foods and tools by producing special products such as honey, rattan, or large game meat for trade. Some work part time for nearby farmers and pastoralists. Others maintain gardens, growing domesticated crops during certain seasons of the years. Finally, a few groups maintain herds of domesticated animals. Panter-Brick et al. (2001) suggest, however, that the actual percentage of those cultivated products in diets of hunter-gatherers is generally very low.

Critiques of typological definitions of hunter-gatherers have recently come from archaeologists in two distinct theoretical camps. Evolutionary archaeologists argue that social types are essentialist and do not reflect that fluid nature of human cultural evolution where change is constant (O'Brien and Lyman 2000). The primary goal of study within this framework is gaining an understanding of evolutionary origins of variability in cultural characters ranging from technologies to foraging strategies.

Archaeologists espousing a social theoretical framework have been more explicit in their critique of hunter-gatherers as ahistorical types (Sassaman

and Holly 2011). These archaeologists argue that hunter-gatherer societies as reconstructed from archaeological data or witnessed in the ethnographic record are the outcomes of history and thus continuously variable. While they have so far avoided some of the excesses of the "Revisionist" school of hunter-gatherer studies (Jordan 2008), they still seek to identify the impacts of historical contingency and individual/group agency on the history of small-scale human groups traditionally identified heuristically as hunter-gatherers.

Historical Background

Archaeological perspectives on hunter-gatherers have changed significantly over the past two centuries. In reviewing historical change in archaeological perspectives, it is critical to recognize that current perspectives are highly diverse, with many archaeologists still engaged in research drawing from older theoretical views. Social Darwinist views generally held that human societies were locked into particular stages of cultural evolution by mental constraints (Kelly 1995). If this was the case, then modern groups committed to such practices as residential mobility, foraging for non-domesticated foods and mandatory food sharing could be labeled survivals from the ancient past, held in place by their inherent inability to rise to a "higher" status. Change could only come with evolution of the brain or by replacement by another group existing at a different cultural level. While most twentieth-century scholars rejected the racialist and ethnocentric elements of social Darwinism, the presumption that historically recent hunter-gatherers represent survivals from the ancient past remained viable. Ethnoarchaeologists, for example, seeking analogies between the present and the past sought out examples of modern people still living in a state close to the Paleolithic. Practitioners of human behavioral ecology in archaeological research today have been critiqued for making such assumptions (Lee and Daly 1999).

The neoevolution and cultural ecology theoretical paradigms brought different perspectives on the nature of change in hunter-gatherer societies. While hunter-gatherers were still viewed as the original form of culture, there was a new perception that cultural change did not necessarily require biological evolution. Now change was driven by "prime movers" forcing hunter-gatherer groups into new, and sometimes less comfortable, modes of existence (Kelly 1995; Jordan 2008). A favorite topic was the transition from hunting and gathering to agricultural modes of existence. Some processual archaeologists influenced by these theoretical models looked to external causal factors such as population packing and environmental change, while others looked to internal processes such as technological innovation (Bettinger 1991; Kelly 1995).

The "revisionist" school painted hunter-gatherers as embedded in complex global web of relationships between human populations with widely varying political and economic interests. In accomplishing this, it offered a significant critique of so-called "pristinist" and "generalist" theories (inclusive of cultural ecology, neoevolution, processual archaeology, and human behavioral ecology). In its most radical form, the revisionists argued that the hunter-gatherers are the rural poor, the losers of Colonial and post-Colonial era struggles. Revisionist theorizing led to a significant new range of archaeological studies, not aimed at defining in situ change but looking at larger scale interactions and impacts of culture contact (Schrire 1984). However, the perception that modern hunter-gatherers were simply marginal survivors of the colonial era was not satisfying to all and led to significant debate, particularly over the interpretation of Kalahari hunter-gatherers (Jordan 2008).

An important outcome of the revisionist debate was the recognition among archaeologists that hunter-gatherers played a more active role in their own histories than had previously been given credit. Sassaman and Holly (2011) outline several means by which hunter-gatherers may be viewed as political actors interacting with wider social, political, demographic, and ecological forces to affect their own histories. Most fundamentally, these social theorists allow hunter-gatherers agency, positioning themselves for

social, economic, and political gain. They also recognize the potential for hunter-gatherers to engage in alterity or practices designed to write and rewrite their own histories. T.R. Kidder's studies of Poverty Point, a massive residential and ceremonial site occupied by hunter-gatherers in the southern United States, make this point particularly well.

Evolutionary archaeologists are not entirely at odds with the positions taken by social theorists. Both recognize the roles of agency and context in the development of history. Their goals differ in the sense that evolutionary theorists seek to understand the evolution of cultural characters, in essence ideas manifested in material things. Social theorists remain more interested in the motivations and practices of the cultural actors. Both seek to understand variability in hunting and gathering societies. Indigenous archaeology has brought additional views of hunter-gatherer variability (Lee and Daly 1999).

Key Issues/Current Debates

Several research issues are actively debated among hunter-gatherer archaeologists today. A fundamental issue that is now hotly debated concerns the evolution of *Homo sapiens* and the development of recognizably modern hunter-gatherer cultural patterns. While all researchers recognize that this process happened in Africa during the past 300,000 years, scholars differ in their opinions on the processes of change and the very definition of modernity in hunter-gatherer contexts. Two positions seem to have emerged. One suggests that the culture of modern hunter-gatherers, as characterized by the Upper Paleolithic of Africa and Eurasia at c. 10–50,000 years ago, could only evolve with biological changes to the brain between about 300,000 and 50,000 years ago. The opposing model suggests that the modern human brain was likely in place by c. 200,000 years ago, with the implication that the emergent Upper Paleolithic pattern was largely the result of cultural evolution.

Hunter-gatherers are at the center of research and debates over many of the world's great population expansions, including the dispersal of early *Homo sapiens* out of Africa, peopling of the Americas, and the movement of Thule Inuit groups across the North American Arctic. Common issues debated in each case concern timing and number of movements, group identities, and causal factors. Outcomes of New World research programs are pointing to complexity in the number, nature, and timing of the major movements. Social/agency theorizing has actually led to some breakthroughs, for example, in Thule Inuit archaeology. Scholars now recognize that the initial movement was probably driven primarily by individuals and groups seeking new sources of iron in the eastern portion of the Canadian Arctic rather than simply seeking to enhance their subsistence base (McGhee 2005).

Subsistence variability and intensification remain prominent topics in the literature, particularly associated with western North America, the eastern Mediterranean, and portions of East Asia. Debates have centered the economic and social logic behind prey choice decisions (Broughton and Cannon 2010). Scholars generally favor economic rationality as best understood using the diet breadth model of human behavioral ecology. However, an increasing number of researchers are offering alternative social perspectives. A good example of this is the debate over the role of costly signaling in the record of ungulate predation by hunter-gatherers of the desert west in North America. Another good example is the research and discussions associated with hunter-gatherer subsistence intensification in the millennia preceding the development of agriculture in the eastern Mediterranean region.

Emergent social complexity has been a central debate among hunter-gatherer archaeologists since the 1980s (Price and Brown 1985). The largest number of scholars seeks covering law-type explanations to the development of social inequality. Processual archaeologists look to underlying resource inequities between groups. Human behavioral ecologists base their models on adaptive decision making regarding optimum use and control of resources using sophisticated mathematical models. Political ecologists and evolutionary psychologists link emergent

inequality to the agency of persons with particular personality types (e.g., aggrandizers). Some social theorists and evolutionary archaeologists have proposed historical models arguing that inequalities arose in some places as historical accidents (Sassaman and Holly 2011). Inequality in hunter-gatherer contexts has been studied and debated most heavily in North America's Western Arctic, Pacific Northwest, California Coast, and Southeast regions, along with portions of Europe, the Near East, and East Asia.

International Perspectives

International scholars have a long history of contributions to hunter-gatherer studies in archaeology (Barnard 2004). Marxian perspectives on hunter-gatherers have been prominent across much of Eurasia (particularly Spain, Russia, and China) during the past century. Western perspectives (e.g., processual archaeology) have been important in the research of scholars in Western Europe, India, and Japan since the 1960s. Processual archaeology has also been influential in Australia and a number of South American countries. In the past two decades, international theoretical perspectives on hunter-gatherers have undergone a significant change with the rise of post-processualism in Western Europe and the development of indigenous archaeology in a number of other places. The rise of indigenous hunter-gatherer archaeologies has been particularly prominent in Australia, South Africa, and North America (Lee and Daly 1999) and has offered the opportunity for archaeological researchers to combine best elements of Western science with traditional knowledge of indigenous groups.

Empirical contributions are widespread around the globe. African scholars have for decades offered critical insight into the human evolution and the development of the world's earliest foraging societies. South Africa has also been the place where the most intense debates over the nature of historical hunter-gatherer societies have taken place (Lee and Daly 1999). European hunter-gatherer research continues to offer significant contributions to human evolution, currently addressing issues of Neandertal adaptations and extinction, Upper Paleolithic variability, and later hunter-gatherer interactions with early farmers. Asian scholars continue to offer new insight into forager-farmer transitions, maritime adaptations, and early Arctic adaptations and population movements. Australian researchers have pushed back dates of Australian colonization and have made important strides in understanding migrations, desert adaptations, and sacred landscapes. South Americanists continue to offer insight into hunter-gatherer engagements with rainforest ecosystems, adaptations to remote isolated environments (Patagonia), early use of marine resources, emergent social complexity, and early population movements in the Americas.

Future Directions

Archaeological discussions of hunter-gatherers will continue to emphasize the solving of major problems associated with human origins, migrations, subsistence variability, and social identity and change. However, these discussions will be increasingly impacted by a number of additional theoretical and political undercurrents.

Hunter-gatherer archaeology will benefit from a close consideration of commonalities between social/agency and evolutionary schools of thought (Jordan 2008). Each offers significant opportunities for insight into variability in hunter-gatherer societies, with a common focus on history of human cultural practices. Human behavioral ecology will also want a seat at this table given its interest in defining the microeconomic logic of human decision making. An important outcome of these discussions will be a demonstrated utility in expanding our understandings of particular histories of indigenous hunter-gatherer groups. Ecological researchers need to pay particular attention to strategies used by indigenous hunter-gatherers to actively manipulate resources within their environments. The time of ancient hunter-gatherers as

passive users of nature's offerings should be long gone.

Gender archaeology will be increasingly critical for comprehensive reconstructions of the past. Defining gendered activity variability in the archaeological record remains a daunting task, particularly when working with very ancient materials (e.g., Paleolithic). Recognition of gendered activity differences is more easily accomplished in later dating contexts where ethnographic analogies are more easily made. For example, on the floors of late precontact Pacific Northwest houses, it is possible to recognize spatial distinctions between hearth- and bench-associated activities, respectively, linked to female and male tasks. However, archaeologists have made significant advances to the point that discussions are even underway regarding changes in gendered activity structure between Middle and Upper Paleolithic camps.

Landscape archaeology will become central to reconstructing hunter-gatherer belief systems, land use practices, political relationships, and economic systems. As an increasing number of archaeologists are recognizing, hunter-gatherer landscapes carry meaning that goes well beyond that of ecology to include a wide range of sacred and spiritual connections. While ancient religions of hunter-gatherers have in many ways remained beyond archaeology's grasp, analysis of symbolic systems across landscapes offers the potential for significant new insights. This will provide more opportunities for archaeologists to advance our understanding of hunter-gatherers beyond ancient economists to more fully engaged human beings equivalent in cultural complexity to those of agricultural societies.

Achieving a comprehensive understanding of past hunter-gatherers will require knowledge beyond the standard training received by many archaeologists. Indigenous archaeologies offer the opportunity to gain new insight into aspects of the archaeological record (e.g., symbols, sacred connections, and traditional practices) not always recognized. Engagement by and with those with traditional knowledge can lead archaeology into entirely new worlds of the past. Indigenous archaeology also offers the opportunity for indigenous people offer their own conclusions about their past, something long overdue in many parts of the world. Archaeology thus becomes not just a science of the past but also a tool for cultural heritage research and education.

The Hunter-Gatherers' Riverine Mound Builders from the Brazilian Atlantic Forest in the Southeast

Cláudia R. Plens
Department of History/Laboratory of Archaeological Studies/Center of Forensic Anthropology and Archaeology, Federal University of São Paulo (UNIFESP), São Paulo, Brazil

Introduction

In Brazil, the mound-building cultures are among the oldest and the longest. Since the end of the Pleistocene until the last millennium before our era, these constructions were scattered throughout countless habitats, certainly with very distinct cultural particularities among those building societies that inhabited different regions in different periods.

Given the importance of these sites, for decades, most studies in Brazilian archaeology have focused on the understanding of the shell mounds, *sambaquis*, found along the Atlantic coast. However, despite the fact that *sambaquis* in inland areas have been located throughout the twentieth century, little attention has been given to their research and study. Generally, these riverine *sambaquis* were mentioned sparsely in the archaeological literature, described as ancient sites with old pottery production of approximately 7500 years BP to the Taperinha site in Northern Brazil (Roosevelt 1991, 1995).

However, in a very specific area in the south of the state of São Paulo, in southeast of Brazil, this picture is different. Research over the last 20 years points to a singular cluster composed of 40 fluvial *sambaquis* in a mountainous region cut by one of the few large basins that cross the Serra do Mar on the west/east axis. In a region of confluence of rivers in the middle of the Atlantic Rain Forest, close to other pre-colonial archaeological sites of the interior and also of large *sambaquis* from the coastal zone, the riverine *sambaquis* of the Ribeira Valley, in the state of São Paulo, is a reference in the cultural settlement with longer cultural continuity in South America. Dating around 10,000 years, they have become strategic sites for the understanding of the occupation of Brazilian southeastern area during the Holocene. The series of dates obtained for understanding the settlement setting of the riverine *sambaquis* associated with a detailed case study, a site with better preservation, in a geographical and chronological intermediate position. This brought information about the formative process of riverine *sambaquis* that later could also be observed in coastal *sambaquis*, in addition to allowing a broader debate on the relationship between the riverine *sambaquis* and inland and coastal groups.

Definition

For this discussion it is necessary to know that on the Brazilian coast, the most visible and numerous archaeological sites are the *sambaquis*, very specific kinds of shell mounds. In order of hundreds, these sites are artificial hills of varied dimensions (from 50 to 1000 m in length and 1 to 30 m in height), whose sediment is composed by more than 80% by shells of bivalve molluscs (Figuti 1991).

Historical Background

According to historical records, many *sambaquis* were quarried for colonial buildings; more recently many have been destroyed for the sake

of the expansion of coastal cities (Garcia 1972; Uchôa 1982). The *sambaquis* have complex structures that demonstrate building processes that varied between a few to hundreds of years of construction. In the past, archaeological literature recognized the existence of coastal *sambaquis* from the state of Espírito Santo to Rio Grande do Sul (southeast to south), but some *sambaquis* are also found spread on the north and northeast coast. About this occupation Figuti (2014) points out that there are two major clusters of coastal sites:

1. The northern *sambaquis*, found near the equatorial coast, or the Amazonian seashore, on the states of Pará and Maranhão
2. The south-southeast *sambaquis*, located on the tropical and subtropical latitudes

Regarding the first area, in spite of its importance for the beginning of the ceramic production in South America (the tradition Mina ceramics with 7500 years BP), just a few studies were developed on them pointing out and revealing those sites were built between 7000 and 900 years BP (Roosevelt 1991, 1995). On the other hand, long-term research carried on the south-southeast sites have shown they are preceramic fisher-gatherer sites, built between 8500 and 1000 years BP. More than 300 *sambaquis* in this area had no evidence of pottery.

Focusing on the occupation of the Brazilian southeast region during the archaic period, it is possible to note a contrast between the shore and inland. Dense at the coastal plains, where hundreds of *sambaquis* are found in the Ribeira de Iguape upper valley, in the South of São Paulo state, something different is observed: dozens of small mounds composed mostly of land snail shells, the riverine shell mounds.

The riverine *sambaquis* are in a subtropical area between 23° and 24° latitude S. They are spread over three areas of the Ribeira Valley (Barreto 1988): the south area, the Jacupiranga basin; the north area, which comprises the Juquiá basin; and the west area, which covers the medium-high Ribeira, near Itaoca (Fig. 1). These areas are in the Serra do Mar, a mountain range that marks the boundary between the sea-level coastal plain and the inland plateau. Its mean altitude varies from 500 to 1300 m. Before the colonization, Serra do Mar supported a rich and highly diversified ecosystem, composed mainly by a lush tropical rain forest, called Atlantic Rain Forest (*Mata Atlântica*).

According to Barreto (1988), the specificity of these areas would suggest an integrated system of settlement. Because of their proximity to big rivers, and the dates believed to be later than the coastal ones, the hypothesis of a coastal migration from the rivers to inland in order to reach better economic resources has been suggested.

She also suggested that it is possible to find some similarities between coastal and riverine *sambaquis* as a result of the coastal migration. This includes construction of the same kind of structure (the shell mounds), although on a different scale, as well as finding faunal remains from the coast in riverine *sambaquis*. In the riverine *sambaquis*, as in the coastal ones, there are a high number of burials. Thick layers composed of land snail shell form circular and convex shapes over the ground which can vary in size from 500 to 1900 m^2 (Figuti ibid).

The faunal remains found in the riverine *sambaquis* are mostly composed of land snail shells of *Megalobulimus* spp. and bones of terrestrial mammals. Fish, amphibian, bird, and reptile remains appear with variables and minor frequencies. It has been suggested that this assemblage could reflect the main diet of that population.

The riverine *sambaquis* present an abundant industry of faunal material (bones, teeth, antler, and shell), mostly used for projectile tips and adornments. Although few, the sea faunal remains as shark teeth beads, ray spine tips, and shells are present on these sites. The lithic industry remains are also abundant and are characterized by knapped tools and polished artifacts as arrowheads, mortars, and axes, which show significant techno-typological and quantitative inter-sites variations.

Key Issues/Current Debates

A project with the title of *Archaeological and Geophysical Investigations on Riverine Sambaquis of São Paulo* (IAGSFL) has been developed from 1999 to 2004 and carried on by Levy Figuti and Paulo DeBlasis from the Museum of Archaeology and Ethnology of the University of São Paulo, Brazil.

This project aimed at investigating the São Paulo state riverine *sambaquis* from different methodological approaches: geophysical, archaeological, and bioarchaeological (Figuti 2004). Regarding the structural and cultural characteristics of these sites, the project pointed out the preference of these groups for a settling of these sites on plains or low lands, with exceptions: some few sites are located on the top of mountains or valleys far from water resources.

This project generated a series of radiocarbon dates for 18 sites (Fig. 2); it was then tried to obtain samples from top and bottom of the sites from Jacupiranguinha (5), Juquiá (3), and Itaoca (10) areas (Map 1). According to Figuti et al. (2013), through examining the graphic and the table (Fig. 2), it is possible to distinguish three chronological assemblages or periods. The early period (10,500 to 9000 years BP cal. age) is represented by two sites from the south/Jacupiranguinha area. A millennium later, the second period (8000 to 3600 years BP cal. age) appears to be the riverine *sambaquis* expansion, counting nine sites in the three areas. 2000 years later, during the third period (1700 to 1000 years

The Hunter-Gatherers' Riverine Mound Builders from the Brazilian Atlantic Forest in the Southeast, Fig. 2 Radiocarbon dates of riverine *sambaquis* obtained by IAGSFL. (Source: Figuti 2004)

BP cal. age), the sites are only at the western/Itaoca area. The authors suggest the expansion starts from the south to the north around 8000 years. Moreover, around 4500 years, the riverine *sambaquis* appear in the western area, and this place seems to be their last redoubt.

The critical point is that this group of sites has endured for 9000 years and seems to rival the coastal *sambaquis* (8000 years), providing a rare South American context of continuous human settlement occupation for almost all of the Holocene. The evidences from sites of the second and third periods are not conclusive on the genetic affiliation of the riverine *sambaquis*, but culturally they became unique, distinct from other inland groups and from the coastal *sambaquis* (Plens 2007). Overall, the series of dates show that the riverine *sambaquis* inhabitants in this area are among the earliest ones already known from all the territory, where is located the earliest burial in the São Paulo state – burial II – from Capelinha site (8869 years BP Beta 153,988) is the earliest one in the São Paulo state.

The early date associated with the craniometric data has indicated to be a paleo-indigenous occupation (Neves et al. 2005). According to the authors, the cranial morphology of this individual does not fit the mongoloid pattern, like other individuals of coastal and fluvial populations but, on the contrary, would have similarities with the cranial morphology presented by the individual of Lagoa Santa, Minas Gerais State (Southeast Brazil).

Given the original data generated by these investigations, the relationship between coastal and riverine *sambaquis* could be better understood. All the particularities of the riverine *sambaquis* were compared with the well-known data available from coastal *sambaquis*. Unfortunately, the Umbu Tradition has no well-preserved remains, other than lithic, in order to make a proper comparison with this group.

The IAGSFL identified the Moraes site as an archetypical riverine *sambaqui*, the mound shape was very distinctive and well preserved, and on the exposed surface was observed only the *sambaqui* occupation (frequently the riverine *sambaquis* were reoccupied by other hunter-gatherers and ceramists). Therefore, it was chosen for detailed research. In 2002, doctoral research by Cláudia R. Plens started to investigate the formation process of a riverine *sambaqui*, emphasizing questions related to food archaeology, from zooarchaeological and carbon and nitrogen analysis of human and faunal remains. The Moraes site was selected to obtain a global understanding of the formation process of a riverine shell mound due to its geographical position, in the middle among the other riverine shell mounds. In addition, it is the most preserved site of the medium period (6000–4000 years BP) and has better burial preservation compared to other sites. From the comprehension of the formation process of this site, it was possible to correlate the data and interpret the riverine shell mounds in the Ribeira Valley.

The Moraes Site

The Moraes site is located aside Moraes stream, tributary of São Lourenço river, in the municipality of Miracatu (UTM 23 J 0256908/7313340).

In the south area of the site, there is a granite/gneiss bedrock and an irrigation ditch; in the east we find the Moraes stream and in the north a plain terrain. In the west (north-south direction), a road has been built, exposing the site profile.

Nowadays, the site presents an elevation with 30 m of diameter and 2 m height all covered by low vegetation, and it is located in the middle of a banana plantation. In the last few decades, diverse plantations have been placed above the site. These plantations caused a series of taphonomical processes, which were particularly intense on the most recent layers.

The site was built above a paleobeach with alluvial sandy-clay sediment formed by Moraes stream. It is possible that this beach had higher dimensions than nowadays. However, this paleobeach is thicker under the archaeological site today because of the site protection from intemperisms. The paleobeach is discreet on the surroundings of the site due to intemperism and human actions that impacted the entire area.

On the top of the beach, there are four archaeological layers that compose the Moraes site (Profile 1):

1. Dark sandy-clay layer. Responsible by the cover of the site, this layer presents low quantity of archaeological remains and higher quantity of rubbles bigger than 1 cm. Its thickness varies between 10 and 30 cm.
2. Dark clay-sandy layer. Land snail shell concentrations were found at this layer and a high quantity of archaeological remains (lithic, osteodontokeratic, and malacologic artifacts and faunal remains). It was found high number of human burials. Its thickness varies in general between 50 and 100 cm.
3. Light gray clay-sandy layer. This layer has a similar composition on archaeological remains. Its thickness varies between 30 and 50 cm.
4. Yellow-orange clay layer. Part of the "paleobeach" is also compounded by sediment decomposition of the matrix rock next to the site. From an archaeological perspective, this layer is almost sterile; however, the first burials were deposited in this layer (Fig. 3).

Carbon dates on burials from different places in the site indicate that the site was built over a period of 2000 years (6000–4000 BP). Out of 51 excavated squares, 20 of them (39%) contained 41 funerary graves with single, double, and multiple burials. Due to disturbances in the funerary contexts, it was possible to identify the form of only 20 burials: 14 primary burials and 6 secondary burials. Among the primary burials, we could find double or multiple burials, and the most frequent position of the skeletons was that of lateral decubitus, followed by dorsal decubitus and even crouched position. Among the secondary burials, the osteological remains were arranged in small circular or oval pits.

Almost half of the burials presented some associated funeral furniture: ocher, large pebbles, howler monkey teeth collars, and polished axes (Figuti 2004).

A peculiar feature of this site is the infant burials. Children burials were found in all archaeological layers. We notice a greater tendency to place funerary adornments with the subadults (Plens 2007).

The faunal assemblage from the Moraes site was recovered from excavations carried out from 2001 until 2004, through artificial level of 10 cm; the remains were collected during the digging and from systematic sieving (screen of 4 mm).

Two indexes were considered for this report, Number of Identified Specimens (NISP) and the Minimal Number of Individual (MNI). The purpose of this analysis was to use the fauna's MNI as a general proportion estimative of the fauna assemblage by identified anatomical side in comparison with the NISP, to discuss amphibious and

The Hunter-Gatherers' Riverine Mound Builders from the Brazilian Atlantic Forest in the Southeast, Fig. 3 Moraes site profile

mammal proportion (the most abundant classes present in the Moraes site).

Bones and permanent teeth samples of human individuals from Moraes site (6000–4000 years BP), Capelinha site (9000 years BP), and Estreito site (3000 years BP) were submitted to $^{12}C/^{13}C$ (^{13}C) and $^{15}N/^{14}N$ (^{15}N) analysis performed by *Beta Analytics Laboratory.* Also, faunal bone samples (mammals, amphibians, and fish) from Moraes site were submitted to the same laboratory for the same kind of analysis. In order to have the (^{13}C) and (^{15}N) stable isotopic signature of the land snail *Megalobulimus* sp., one alive specimen was taken from another riverine shell mound (Laranjal site), 5 km from the Moraes site. The *Megalobulimus* sp. specimen flesh was first lyophilized at the Faculdade de Ciências Farmacêuticas, Departamento de Tecnologia Bioquímico-Farmacêutica (USP), grounded at the Zooarchaeological Laboratory at the Museu de Arqueologia e Etnologia (USP) and then submitted to stable isotope analysis at CENA (USP).

The sambaqui sediment analysis indicates the predominance of the land snail shell, with an average ratio of 45.6%. The other significant components are bones (average ratio, 5.55%), clay (16.3%), and sand (32.3%). The riverine sambaqui sediment has a lower average density compared to the coastal ones; the main reason is that the *Megalobulimus* shell is large (6–10 cm long, 3–5 diameter) but lightweight, generating uncompressed deposits.

34,160 vertebrate fragments of all sizes and classes were identified on the faunal assemblage from the excavation of 50 m^2 of the site. The invertebrate remains (except *Megalobulimus*) recovered were mostly freshwater mussel shells (genus *Diplodon*, NISP = 2035) and some sea shells (59 oysters and 34 quahogs) and few crab pincers (7).

The evaluated fauna NISP indicates the predominance of mammals, followed in decreasing order by amphibious, bird, fish and reptiles. Taking into account that the riverine shell mounds are settled in a tropical rain forest environment, the Atlantic Forest, the high frequency of mammal (68%) is not surprising. However, the important presence of amphibious is an uncommon fact in archaeological sites (Fig. 4).

The Hunter-Gatherers' Riverine Mound Builders from the Brazilian Atlantic Forest in the Southeast, Fig. 4 NISP of vertebrate faunal assemblage of Moraes site by class of animals

The most recurrent fish remains in the collection came from freshwater fish, as catfish and suckermouth catfish (Pimelodidae *and* Loricariidae families). The amphibians could not be identified by species, just as member of the Anura order. Among the reptile, turtles and tegu lizard (*Tupinambis teguixin*) were identified. The bird remains could not be determined by specie. The fragments of those classes of animals were found in all squares and levels of the Moraes site.

On the other hand, the remains of mammals could be recognized in larger number of species. The mammals NISP is 2343 among which it was observed 198 individuals through MNI index (11 species and 2 orders). In decreasing order of mammal NISP are armadillo, howler monkey, peccary, spotted paca, guinea pig, Brazilian agouti, Brazilian tapir, opossum, and brocket deer, which presented different patterns of bone preservation. The remains of the armadillo

are predominantly represented by the preserved scutes. The major NISP is represented by the armadillo (*Dasypodidae),* which is the animal that presents the highest number of scutes by individual. However, the MNI index (calculated through bones) changes this species position to the 8th place, representing only five individuals.

In general, there is no variation between NISP and MNI indexes for the other species, except for the Brazilian guinea pig (*Cavia aperea*), the most significant case. The Brazilian guinea pig occupies the fourth according to the NISP, but the MNI grants it the first position as the most present species among the remains (Fig. 5).

The howler monkey (*Alouatta* sp.) presented more cranial evidence, probably due to higher conservation degree especially on teeth. Peccary (*Tayassu* sp.) remains follow the howler monkey with higher quantity of identified specimens from skulls, especially teeth. However, in this case the elevated presence of astragalus and calcaneus indicates that this animal might have been taken as a whole to the site.

The spotted paca (*Agouti paca*), guinea pig (*Cavia*), Brazilian agouti (*Dasyprocta* sp.), Brazilian tapir (*Tapirus terrestris*), and opossum (*Didelphis* sp.) exhibit higher teeth preservation in comparison to bones. In general, the main cause for the lower NISP for these animals is the high degree of bone fragmentation and also the similarity among rodent bones. The most identified specimens of brocket deer (*Mazama* sp.) were based on bones rather than teeth. In that case, the bone state preservation seems to be higher than for other animals, probably due to the compactness of these bones. The spotted paca was sparsely distributed throughout the site. Big size animals have presented a higher tendency of bone fragmentation, and this is probably the most important cause for the low rate of identified bone elements.

From the 20 graves found in the 51 excavated squares, 41 skeletons were identified. The fauna found in the squares with burials represent 71% (24,255 NISP) of total vertebrate NISP in the Moraes site (34,160 from 51 squares). Observing the faunal distribution, the concentration areas are located very close to the graves, around and above. In general, the analysis of faunal distribution by artificial levels enables us to correlate fauna concentration to burial areas. Even grids with no evidence of burials showed fragments of human bones on the profile, suggesting some connection between fauna and burials in these cases, as well.

Taxa	Popular name	NISP	%	MNI	%

The Hunter-Gatherers' Riverine Mound Builders from the Brazilian Atlantic Forest in the Southeast, Fig. 5 Mammals NISP and NMI from Moraes site

Carbon and Nitrogen Isotope Analyses

The association of identification and spatial distribution of faunal remains with paleodiet, obtained by stable isotopes analysis of carbon and nitrogen from human bones and teeth and faunal bone samples, allowed to develop a discussion about the riverine shell mound group's consumption. Comparative data from the archaeological literature was used to complement the ratios obtained (De Masi 2002; Keegan and Deniro 1988), aiming at amplifying the discussion about stable isotopes from different environments.

The lyophilized samples of *Megalobulimus* spp. were submitted for three repetitions. However, the three values presented relatively similar indexes, and therefore it was selected the intermediary values for the chart construction. The results of stable isotope analysis of carbon and nitrogen of human individuals from three riverine shell mounds with different chronology (Dates: Moraes site (5895 years BP to 4511 years BP), Estreito site (4100–3600 years BP) and Capelinha site (9250 years BP)) (1) presented little variation on values of $\delta^{13}C$ and $\delta\ ^{15}N$ among the individuals: $\delta^{13}C$ (−19.2 and −21.4; pattern deviation = 0.86) and $\delta\ ^{15}N$ (9.6 to 11.9; pattern deviation = 1.04) for human bones and $\delta^{13}C$ (−21 to −23) and $\delta\ ^{15}N$ (11.9 a 12.6) for human teeth. These values, with variation lower than two points, indicate homogeneity in relation to food consumption for these groups during, at least, 7000 years (Table 5). Isotopic results from bones show that human individuals of the riverine shell mounds were a homogenous group, hypothesis corroborated by teeth results. The teeth cluster, not distant from human bone (lower than two points), is explained by the fact that dentine is formed during breastfeeding and, consequently, this fact led to an increase of proteic values (Fig. 6).

According to Lubell and Jackes (1994), stable isotopic data interpretations might occur through the reading of "trophic level effect," in which enrichment indicates the individual relation to the consumed items in 5% in carbon collagen fractioning and between 3% and 4% in relation to nitrogen. From Lubell's collagen fractioning interpretations of food consumption, it is possible to notice that just the spotted pacas (*Cuniculus paca*) have values compatible with the "trophic level effect" cluster of riverine *sambaquis*, among all the other animals analyzed. The other mammals were recovered at the Moraes site, in which collagen could be collected; a higher distance of 4‰ for nitrogen, sometimes reaching 8‰ (e.g., peccary case), was observed. Unfortunately, it was not acquired collagen

preservation for Brazilian tapir, armadillo, guinea pig, and amphibians (Figs. 7, 8, and 9).

Looking carefully at the spotted paca case, it is possible to evaluate that, even though this animal appears on "trophic level effect" cluster of human individuals, this was probably not an important item of the daily food, once zooarchaeological indexes point to a maximum of five individuals by MNI. Spotted pacas are rodents of superfamily Cavioidea, and the Brazilian agouti, spotted pacarana, moco, prea, and capybara eat fruits, seeds, and succulent vegetables.

Unfortunately, there was no collagen preservation for stable isotope analysis for major MNIs, the guinea pig and the amphibians of the Moraes site. Further research may test the hypothesis that this animal was an important consumption item of riverine *sambaqui* groups. In relation to carbon "trophic level effect" of riverine *sambaquis*' human individuals, it is clear that there is no direct relation to C_3 or C_4. Its positioning is above CAM plant cluster. These plants are still unknown from the consumption perspective, and more studies on that must be carried out.

Discussion and Future Directions

After 6000 years BP, with the increase of humidity and density of the *Mata Atlântica Rain Forest*, the fauna diversification allowed the *sambaqui* groups to obtain new species as resource from this environment [e.g., monkey, an arboreal animal that needs a close forest to dislocate through branches, appears in high quantity from bottom to top of the Moraes site (6000–4000 years BP)].

Nonetheless, stable isotope data indicates that even though mammals had a significant presence in the Atlantic Forest, and in particular at the Moraes site, meat consumption of mammals does not seem to be intense. Data indicates that these mammal species were not consumed in every day meals but in a sporadic and restricted manner as a more elaborate meal, for instance, in celebration episodes, such as feasting meals during funerary rituals, or offerings to the dead. Moreover, isotope data indicates that although in high quantity in riverine *sambaqui* layers, the *Megalobulimus* land snail did not represent an important item of consumption. It appears that this resource was employed as a construction

The Hunter-Gatherers' Riverine Mound Builders from the Brazilian Atlantic Forest in the Southeast, Fig. 9 Stable isotopes analyses on human bone and teeth and faunal bones

material rather than being present in the *sambaqui* as a result of "kitchen midden." The high intensity of resource catchment must have been caused by the necessity of bone preservation for the maintenance of the sacred place.

Lithic analysis led to some discussion in this perspective. The elevated burning traces in the lithic assemblage indicate high pit fire temperatures. However, just some thin layers of fire were found, and they could not have been enough to burn the quantity of lithics recovered at the site. This information suggests that lithics had been burned somewhere else and, then, taken and deposited in the site.

Among the lithic assemblage, mortars and pestles were objects with higher intensity of use traces. For this reason, these tools seem to characterize the importance on vegetable resources processing in the everyday life of this group, since they are generally employed on these activities. Disposal recurrence of characteristic daily lithic artifacts in a funerary context reveals the cultural concern of these groups in taking important objects from individuals' lives to the world of the dead.

As the isotopic data indicates the identified mammals from the Moraes site were not consumed as a staple food for this group, then other animals and especially vegetable resources may have played an important role in this perspective.

The comparison of isotopic values from the graph and archaeological literature indicates two hypotheses for vegetable use by this group. As carbon values are positioned inside the cluster related to CAM plants, this may indicate the intense consumption of these plants or an important consumption of both C_3 and C_4. In the last case, the mixed consumption of C_3 and C_4 may mislead the isotopic results taking the results to an intermediary position, above CAM plants values. Further, vegetable resource

Moraes	**8**	**87.5**	**18.05**	**3.5**

importance for riverine *sambaqui* consumption is corroborated by human dental data from the Moraes site.

The frequency and prevalence of cavities were assessed, based on data from eight individuals (one juvenile ±15–20 years old and seven adults ±25–40 years old). The result demonstrated cavity prevalence in the skeletal series in a percentage of 87.5% ({8/7}*100) and cavity frequency of 18.05% ({24/133}*100). From the eight individuals analyzed (5, 6a, 6b, 9, 12, 13, 17, and 35), seven have cavities, with one of these individuals having two extensive cavities (one with total crown destruction and one with 50% crown destruction). The other six individuals had cavities in the root (occasionally they compromised the crown teeth). In terms of media, each individual presented three cariogenic lesions (24/8).

To comprehend the values above, we compare this data with the analysis conducted by Wesolowski (2007: 153) from the coastal *sambaquis: Morro do Ouro* (recent and old layers), *Enseada I*, *Marechal Luz*, and *Itaocara* (ceramic) (Table 8) (Fig. 10).

Data from the table above indicates high cavity prevalence and frequency in the Moraes site individuals. In comparative terms, if coastal *sambaquis'* people present a "generalised consumption of starch consumption" (Wesolowski 2007), it is expected that people from Moraes would have an even high level of starch consumption. The high cavity prevalence and frequency is an uncommon phenomenon for hunter-gatherer groups in Brazil and indicates a diet high in carbohydrate and poor in protein levels.

The Formation Process

In relation to the formation process of the Moraes site, the results of the analysis indicate an increase in the amount of lithic material, osteodontokeratic and faunal (vertebrate) artifacts, and shells in relation to proximity to burial areas. The burials show differences in the body positioning, but there is homogeneity regarding burial structures, regarding the opening of delimited pits, recurrent deposition of shells from different environments (fresh and marine water), organized spatial distribution and coverage of fungal structures by *Megalobulimus* shells, in all areas and layers of the Moraes site, including layer 1.

The first groups to construct the mounds, 6000 years ago, chose an area where a paleobeach formed by a sandy-clayey sediment had been formed. On the south and east sides of the site, the paleobeach and rocks formed natural structures that helped protect the funerary mounds, thus preventing material from being carried into the stream. In that time, the stream was most likely larger due to the higher climatic humidity and the highest marine eustatic level (Plens 2007/8). This space is constituted by a natural landfill of sand and rocks, in an area of high humidity, which seems to have been the attraction of the place.

The burials followed a pattern: shallow graves were excavated for the deposition of the bodies or small pits for secondary burials. In each case, the grave was covered by a mix of sand, clay, and shells.

The materiality of the funerary rituals indicates that the preparation of the body and the interment process took a long time to be performed. The great flexion to which some bodies were

submitted in their graves indicates that there was a preliminary period for soft tissue decomposition to begin, allowing the bodies to be compressed in the graves (usually there was preservation of the ligamentous connections that maintained the anatomical connection of the skeletons). In these cases, the transport of the body, or bones, seems to have taken place from a temporary funerary area to the permanent one.

The burial rites involved the covering of bodies with ocher. In some bodies there is subtle evidence of this process, suggesting that the ocher has been used directly on the individual's skin and, with soft tissue decomposition, the dye has impregnated the bones. In other cases, in contrast, the impregnation of the pigment in the bones is high, which raises the hypothesis that in these cases, the painting was done directly on the bones. In order to perform this procedure/this act of the funerary rituals, the living should have to wait for the processes of decomposition of the flesh of the deceased to occur so that the bones could be handled later.

Innumerable artifacts were placed as grave goods, sometimes to the side and sometimes above the individual and/or on the grave. Recurrent throughout the site was the use of freshwater shells and a few items from mangrove and the seashore in the areas of burials, both on the floors where the bodies were disposed and on the mound structures that covered them.

The spatial dispersion of the fauna (Ferraz 2006; Plens 2007) shows that the largest percentage of fauna and 75% of the osseous industry was inside the burial layers.

Despite the numerous taphonomic processes that took place in the site, burials no. 5 and no. 27 present clear indications of animal offerings in the funerary space. In burial no. 5, peccary (*Tayassu* sp.) calcined bones were located associated with the adult human body. Near the burial no. 27, two concentrations of howler monkey (*Alouatta* sp.) were found, indicating that this animal was offered during mortuary rites (Plens 2007).

In the floors built for the deposition of burials, as well as above them, there is evidence of small fire pits without associated lithic structures. Several layers above the burials have evidence of burning, suggested by the presence of small coals and burning ground, which meant that, in some areas, fine soil lens became concreted.

The low number of bones with different degrees of burning, in contrast to the high number of burned lithic material, suggests that the main function of the fires was not to prepare the meat as food. The thickness of the firing lenses, sometimes a maximum of 1 cm, represents pit fires that have burned fast, indicating insufficient time for baking cakes or roasting meat. In addition, cut marks are very rare in the analyzed fauna.

After the opening of a grave, some special elements were laid, often bivalve freshwater shells, and a few marine bivalves and crustaceans, as well as adornments (tooth beads necklaces) and animal bodies, which were placed as offerings. Occasionally, there seems to have been pit fires on the side or above the layer that covers the body. Around the grave often mortars and other large lithic pieces were placed, which seems to be delimiting the burial, especially near the skull. Then the burials were covered by a heap of land snail shells, except in the burials of the layer 1.

According to the sedimentological analysis (Teixeira et al. 2014), the heaps mixed with sediment of alluvial origin, rich in clay, were used to cover these mounds, probably, to give stability to the shells.

On the other hand, the homogeneous distribution of flakes throughout the site indicates that there was no concern about placing them in specific spaces, suggesting that these materials were brought along with sediment from other areas outside the site and randomly accumulated.

According to data from the excavation and the site profile, there are no archaeological lenses that indicate successive returns for the celebration of other funeral rites, dedicated to the dead already buried, once the mound was covered.

The dates indicate that the first burials occurred on the paleobeach in the central part of the site, in a short time. However, the overlap of 400 years between the oldest burials of the central area and the burials of the northern periphery of the site reveals that the funerary area grew laterally with the extension of the mound structure to the sides.

The C14 dates from the upper burials at the central area indicate they were made 1000 years after the first ones, suggesting the beginning of the construction of the site. The dates of the later burials and their overlapping disposition configure the final structure of the site after 2000 years of activity. After a few hundred years, since the paleobeach was occupied by innumerable burials, the continuous funerary activities on the site led to the reoccupation of the space over the most ancient burials. In some cases, successive burials were performed without transgressing the space.

However, the opposite situation has occurred as well. The interpretation of the profile associated with the burial structures and the location of human and faunal bones indicates the opening of deeper graves for the earliest burials which partially interfered in the older structures, and the sediment removed from the graves was dispersed to the surroundings, as in the case of the burials of square F22 (central area).

Zooarchaeological data clearly shows the use of vertebrates and invertebrates related to burial areas in Moraes site formation. The distributive analysis of some species indicates that, in general, the animals were taken as a whole (entirely) to the site. All classes of animals were used in the funerary context, including amphibians which, as seen, were anthropically inserted in the site. In some cases, there are concentrations of bones of a single species indicating the deposition of whole specimens, beside or on a burial, as a funerary offering.

In addition to the intensive use of vertebrate remains for the composition of funerary spaces, the recurrent concern with the treatment of the space dedicated to the dead has made this society to mobilize in search of resources of different environments, such as freshwater shellfish, oysters, and marine crabs. The distributive analysis of this material clearly indicates that the use of these traces had as objective the composition of the mortuary space.

There are cases in which the distribution of the faunal fragments indicates that some areas of the Moraes site were privileged by the use of a high quantity of this material, such as burial no. 20 which received a large quantity of freshwater shellfish in the ornamentation of the burial space. The analysis of distribution of lithic material indicates differences in relation to the area of discard. Large-sized materials, such as mortars, manes, and axes, were located over burial areas (and in some cases scattered on the southern periphery of the site), while the flakes and other lithic refusal were widely dispersed in the site. However, the dispersion of the lytic material does not appear to form chipping areas or any other type of structure or organization; on the contrary, they appear to have been taken and deposited randomly, probably carried along with the sediment used to support the mound of shells.

The sedimentological analysis shows that although layer 1 of the site does not present the same amount of organic material visible macroscopically, the soil contents indicate that this component was important for the composition of this layer.

Taphonomic processes have been very intense in soil evolution in all layers of the archaeological site, and underlying it, through the percolation of P and clay that migrated from layer 1 to the other layers.

During the data treatment, an interesting set of correlations between Ca and Mg to be elucidated was verified: in the archaeological soil, there is an inversion of values between Mg and Ca that does not occur in the profile analyzed outside the Moraes site.

The analysis of the proportion of archaeological components indicates that shells and clay are the main elements in the composition of the layers, being followed directly by sand and to a lesser extent, but steadily, by the bones.

This analysis also indicates a strong correlation with the data obtained by sedimentology with regard to the percolation of clay from the first to the other layers, making the proportion of this component in the last layer higher than in the others.

The Riverine *Sambaquis* and the Mound Construction

If, as noted by several authors (Kneip 2004; Gaspar 2000; DeBlasis et al. 2007), the visibility

makes the coastal *sambaquis* an important element in the territorial control of these groups, in the case of riverine *sambaquis*, the visibility of their constructions does not seem to have had the same importance. The riverine *sambaquis* known today measure a maximum of 2 m in height and are usually inserted within mountainous valleys that prevent the visualization of these constructions from a distance. More than this, the lack of maintenance and cleaning of the riverine *sambaquis* makes the forest cover them, making them an integrated part of the natural landscape of the Atlantic Rain Forest.

The most important process in the construction of the riverine *sambaqui* seems to have been the integration of society in the maintenance and worship of the same monument. It is, therefore, a form of internal social control of these societies, and its execution depends on the time and energy expenditures of the society in the capture of resources of diverse environments (inland and coast) and, also, the network of contact with groups neighbors. About Moraes, it can be said that the process of reusing the same funeral space, for dozens of generations, is indicative of the recognition of an identity, whose link of ancestry is symbolized by the construction of a monument respected by the whole group.

What makes the riverine *sambaqui* monuments is the fact that dozens of generations have worshiped their ancestors in the same space, whose importance was transmitted between generations, especially oral memory, and not the visibility of buildings. As indicated throughout this paper, the main characteristic of the formation of the Moraes site is the construction of small clusters, whose purpose was to perform funerary rites, and where the materials used were mainly *Megalobulimus* shells, sediment transported from other areas, and smaller scale a wide range of faunistic remains of accentuated anatomical and taxonomic diversity, and lytic material and osteodontokeratic artifacts.

This pattern of archaeological site formation seems to be a common cultural denominator among riverine *sambaquis*, given the data generated by the IAGSFL project. Data from the excavations and the reading of the profiles of the sites Estreito, Pavão XVI, and Lajeado IV indicate a great similarity with the Moraes site: numerous burials with archaeofauna (vertebrates and invertebrates) and associated lithics. All other sites, even those with less evidence of burials, such as Caraça and Capelinha 1 and 2 also present clusters of *Megalobulimus* shells, with a large amount of archaeofauna and associated lytic material. In relation to the implantation of the sites, there seems to be a recurrence regarding the exploitation of wetlands.

The Distribution of Riverine *Sambaquis* on the Landscape

Through the surveys carried out so far, the riverine *sambaquis* of the Ribeira de Iguape Valley are distributed in three specific regions: the Jacupiranguinha basin, the Juquiá basin, and the Itaoca region (upper-middle Ribeira). Although the dates are quite diverse, the sites of the Jacupiranguinha basin (where the Capelinha site of approximately 9000 years BP is inserted) occupy an older chronological position between these three areas. The Juquiá basin presents sites with retreated dating, such as the Laranjal site (approximately 7000 years BP), and also intermediaries, such as the Moraes site (between 6000 and 4000 years BP). The Itaoca region has the most recent sites, between 4000 and 1000 years BP.

Considering the spatial distribution and location in the landscape, the Juquiá basin sites appear to form a territorial cluster defined by funerary sites, since in all the sites in question (Moraes, Laranjal, Alecrim I, and Miracatu), the occurrence was observed of burials. In this case, the Laranjal site, the only one located on top of a mountain, would be configured in a central position to the other sites. It is known that the Laranjal site has a dating of approximately 7000 years BP, that the Moraes site was used between 6000 and 4000 years BP, and that the site Alecrim I began to be built when funeral activities in the Moraes site were no longer exercised. In this model, the Laranjal site would occupy the central space in the

occupation of a given territory, and the other sites, such as Moraes, Alecrim, and Miracatu, would position themselves peripherally in this area.

The Riverine *Sambaquis* and the Neighboring Groups

As pointed out by the research, there is a constant relationship between riverine sambaquis and neighboring groups, either with coastal sambaquis through the architectural similarity of the site and in particular of the use of sambaqui as funeral area or with Umbu groups through the applicant, although low, presence of lithic industry associated with these groups.

If the genetic link between riverine sambaquis and one or other neighboring group is not conclusive about the affiliation of riverine sambaquis, culturally they have become unique, distinct from other groups in the interior and coastal sambaquis.

What can be said is that culturally the riverine *sambaquis* constituted groups that became unique, different from the other groups of the interior or coast, and developed a way of life of their own that lasted for at least 9000 years without having, during this time, a similarity to one or another tradition to the point of characterizing affiliation with other cultural groups.

Thus, it is possible to construct a model in which technological exchanges and acquisitions between riverine *sambaquis* with groups of the Umbu Tradition and coastal *sambaquis* characterize a network of intense contacts, and perhaps of interethnic marriages, with neighboring groups over millennia, and that the symbolic burden of bone preservation and social mobilization for ancestor worship comes from an earlier culture that gave rise to coastal and riverine *sambaquis* groups.

Hunting and Hunting Landscapes

Naomi Sykes
Department of Archaeology, University of Nottingham, Nottingham, UK

State of Knowledge and Current Debates

There is an increasing recognition that the study of human-animal-landscape interactions, as reflected in the zooarchaeological, artistic, and historical record, can provide important information about how people engaged with and perceived their surroundings as well as each other. Human responses to wild animals in particular have been shown to reflect individual, social, and cultural attitudes to the "natural world." Some of the most pivotal moments in the human story have been characterized by shifts in the relationship between humans and wild animals. For instance, the concept of domestication not only gave rise to the category of "wild" but also meant that it was no longer *necessary* to hunt in order to obtain meat. Yet people continued to do so. In some periods, hunting was a rare occurrence; in others, it became a frequent pursuit central to popular culture, evidenced by the art and literature of the time.

This entry seeks to review the evolution of hunting and hunting landscapes from the Epipaleolithic of Anatolia to the medieval period of England. Such a wide chronological and geographical remit clearly runs the risk of producing extremely superficial analysis, but conversely, by breaking down artificial spatiotemporal boundaries and considering the evidence from a wider viewpoint, it is hoped that new perspectives will emerge on a subject that has traditionally been compartmentalized by period and region (Cummins 1988; Birrell 1992; Barringer 2001; Hamilakis 2003; Atici 2009; Sykes 2011; Sykes et al. 2011; Arbuckle 2012). In an attempt to give focus to what could easily become an unwieldy subject, this entry concentrates specifically on the evidence relating to the European fallow deer, *Dama dama dama* (Fig. 1). Despite its name, this deer species is not of European origin: it is native to Anatolia but over the last 10,000 years has been transported by people around the world. As such, the cultural biogeography of fallow deer provides a unique opportunity to explore a variety of different hunting landscapes, created as this "wild" species passed gradually from being a free-living element of the fauna of its native range to an exotic species maintained in parks across northern Europe.

Definitions and Datasets

Given that the terms "landscape," "hunting," "wilderness," and "wild" are some of the most nuanced and contested in archaeological and anthropological discourse, it is perhaps best to start by making clear the definitions.

Here landscape is defined not simply as physical geography and environmental conditions, although these are important elements of landscape, but rather as how people perceive and understand their surroundings as a result of their engagement with them. This definition sees landscape and worldview as inseparable, each serving to constitute the other. Movement and mobility are also suggested as vital components of both landscape and worldview: the sayings "travel broadens the mind" and "fear of the unknown" are of direct relevance here. In general terms, mobile groups who travel across, and are familiar

Hunting and Hunting Landscapes, Fig. 1 Male fallow deer (*Dama dama dama*). (Photo: author)

with, wide spatial ranges or those communities involved (directly or indirectly) in long-distance trade/exchange will have a different perception and understanding of their worlds than those who live a more sedentary or insular lifestyle. Insular sedentism allows intense engagement with, and very detailed knowledge of, local surroundings, but as movement reduces, so mental geographies contract, giving rise to infrequently traversed and unfamiliar landscapes beyond the "known realm."

Often these outer realms are conceptualized as the "wilderness." This term is used here not to suggest some primordial landscape untouched by humans; instead, wilderness is defined according to its original meaning: etymologically it comes from the Old English *wildeoren*, meaning *wildern* (wild or savage) and *deor* (animal), denoting an area where wild animals are found in greater numbers. Of course, the term "wild" is also problematic, frequently set in opposition to the other problem child "domestic." This is not the place to deliberate over these two words; suffice to say that, for the purpose of this entry, wild animals are categorized as those that are acquired through hunting.

In terms of hunting, Cartmill's (1993: 197) definition is employed: that hunting is the killing of a special sort of animal, in a specific way, for a particular reason. Cartmill stresses that this killing must be premeditated, preceded by deliberate tracking/stalking under circumstances where it is theoretically possible for the animal to evade its pursuer, and that the death is brought about by direct human violence, without mediation by trap or snare. Such a definition is flexible enough to allow tame or even domestic animals to cross the boundary and become conceptually "wild" through the activity of hunting – e.g., as was seen at Neolithic Durrington Walls (UK) where several domestic cattle and pig bones had flint arrow/spear tips embedded in them, leading Albarella and Serjeantson (2002: 44) to suggest that these domesticates were ritually hunted.

Unfortunately, in the absence of skeletal evidence for weapon-inflicted injuries, it is almost impossible to separate the archaeological remains of animals that were hunted from those that were obtained through other mechanisms. It is, therefore, important to view the zooarchaeological data presented in Table 1 with caution. These data, which review the representation of European fallow deer (*Dama dama dama*) across space and time, need not represent the remains of hunted animals – some of the individuals may have been tamed and dispatched as though they were

domesticates, and we cannot be certain that they were hunted. There are other problems with this diachronic dataset, most notably, that it takes no account of inter-site variations in preservation or recovery. With these caveats in mind, however, the evidence in Table 1 can be examined to gain a broad-brush impression of the rise and fall of hunting cultures, the timing of the westward diffusion of fallow deer from Anatolia through the Mediterranean and mainland Europe, and the associated shifts in the status of the species.

In order to gain greater insights into hunting decisions and issue of seasonality, the demographic composition of the fallow deer assemblages is also considered, where possible. Fallow deer are highly sexually dimorphic, and therefore, osteometrics, derived from the online *Deer Bone Database* (n.d.), have been employed to examine male-female ratios as well as variations in the physical conformation of deer, which itself is related to landscape and environment.

To some extent, environmental conditions – geology, baseline vegetation, temperature, and aridity – are preserved in the very chemistry of the bones, and isotopic analyses of archaeological fallow deer remains can help to reconstruct human-animal-landscape interactions. Genetic analyses may also be useful in this respect, informing on population dynamics and episodes of translocation. At present, however, data from such scientific investigations are of limited availability, and although some reference will be made to them here, more emphasis is placed upon the historical and iconographic record. Artistic and textual evidence is patchy for the periods and regions under consideration but is available for the Bronze Age Aegean (Yannouli and Trantalidou 1999), Archaic, Classical, and Hellenistic Greece (Yannouli and Trantalidou 1999; Barringer 2001), some areas of the Roman Empire (Reinken 1997), and medieval northern Europe, in particular England (Sykes and Carden 2011). Anthropological studies are also employed, not as direct parallels for archaeological societies but rather as a mind-stretching exercise, to provide alternate perspectives on landscape, environment, and social attitudes to hunting (Cartmill 1993; Helms 1993; Ingold 2000; Willerslev 2007). By bringing these sets of evidence together and integrating them with wider archaeological knowledge, it is possible to examine how hunting and hunting landscapes varied across time and space.

The Hunting Landscapes of Epipaleolithic and Neolithic Anatolia

Current zooarchaeological evidence suggests that, as a result of the last glacial maximum (c. 20,000 years ago), the distribution of fallow deer became restricted to Anatolia (Masseti 2002). Certainly it is from this region that we have the best available dataset for analyzing human-dama-landscape relationships in the early postglacial period. Atici's (2009) examination of seven Epipaleolithic assemblages from two neighboring sites (Karain B and Ökuzini caves) in the western Taurus mountains provides a rare insight into the landscapes of the hunter-gatherers who occupied the area between 19,800 and 13,700 cal BP.

These broadly contemporary assemblages, situated just one kilometer apart (Fig. 2), reveal an interesting variation in fallow deer representation: while *Dama* are abundant at Ökuzini, comprising 27.8% of the mammalian material, they are almost completely absent from Karain B, where the assemblage is 99% caprine (Table 1). Admittedly a small number of fallow deer remains are represented at Karain B, but they are all antler fragments, so not direct evidence of hunting. Environmental conditions and topography alone cannot account for the inter-site variation, since both sites occupy the same ecotone with access to a variety of microenvironments – mountain slopes, valleys, the travertine plain, as well as areas of open grassland, marshes, and forest – and an equally wide range of prey. This led Atici (2009) to conclude that the differences in assemblage composition most probably reflect cultural preferences linked to seasonal hunting and mobility strategies. Aging data from the two sites suggest that, at least in the early postglacial phases (Karain B1/2 and OK1), occupation was seasonal, probably from late spring/early summer to October. The caprine mortality profiles also make clear that, although animals of all ages

Hunting and Hunting Landscapes, Fig. 2 Map showing the location of the sites mentioned in Table 1

were represented, those between 2 and 4 years were targeted preferentially.

These data indicate that the Epipaleolithic hunters not only were highly skilled in their abilities to select out particular species and individuals but, perhaps more importantly, were taking a conscious decision about which animals *not* to kill. For instance, given the close proximity and environmental setting of Karain B and Ökuzini, we may assume that similar ranges of taxa were available at both sites; however, at Karain B, fallow deer appear to have been deliberately and persistently avoided throughout the site's 500 years of occupation. Assemblages such as Karain B are usually interpreted in economic terms, as "specialist sites" established to maximize returns from available resources. No doubt, effectiveness in hunting was a concern to the Epipaleolithic hunters, but the idea that optimal foraging was their main concern seems at odds with anthropological evidence pertaining to modern hunter-gather groups.

Across cultures, studies have demonstrated repeatedly that hunter-gatherers tend to perceive their landscape and environment not as economic resource but, in familial terms, as a parent who actively provides for them so long as the hunter-gatherers behave appropriately (Ingold 2000: 67; Willerslev 2007: 42). For instance, they should take no more than they need, are required to share out the resources they receive, and should ensure that they treat the animals with respect at all stages of their interaction – during hunting, butchery, consumption, and disposal (Ingold 2000: 67; Willerslev 2007: 35). If humans behave accordingly, the animals will give themselves up freely to the hunter, and once their soul has been released and reclothed with flesh, it will return to him in the future. However, poor treatment – such as overkilling, unnecessary violence, or wastefulness – ensures that the animals do not return and the hunter is never again successful. In order to coax animals into sacrificing themselves, hunter-gatherers frequently practice mimesis to "become" their quarry so they might better seduce them into giving themselves up. Based on the experiences of modern hunter-gatherers, the idea that fallow deer hunting at Ökuzini, and indeed caprine hunting at Karain B, took the form of an intense interpersonal dialogue is not unreasonable. This would suggest that hunting was controlled and restrained in ways different to those of an optimal foraging strategy. If mimesis was employed, the hunting landscape may even have been seen through the eyes of the quarry – a very different perspective on the world (Willerslev 2007: 106).

Such a situation is easier to comprehend for a period before the arrival of domestic dogs, which are absent from Anatolia before the twelfth millennium BCE (Arbuckle 2012: 210). Without the distraction of dogs, mimesis would have been easier to maintain, an important point given that this form of shape-shifting is often deemed dangerous, potentially leaving the hunter trapped in animal form (Willerslev 2007: 93). Even successful hunting is not without risk however. It is frequently reported, again cross-culturally, that hunters feel deep guilt about their kill and are fearful that the "animal masters" – the spirits who protect the animals – will seek vengeance (Willerslev 2007: 44, 79). If hunting in Epipaleolithic Anatolia was felt to incur a spiritual debt and overkilling was not acceptable, it stands to reason that deliberate non-killing (e.g., the avoidance of fallow deer at Karain B) would have been a prudent statement of respect. The need not to waste hunted animals could equally account for the high levels of bone fragmentation, indicative of intensive processing, seen at both Karain B and Ökuzini (Atici 2009: 22).

Taken together, the data from these sites can be interpreted as follows: that similar to modern hunter-gatherers, Epipaleolithic groups had an intimate relationship with their environment, their hunting landscapes constituted by specific, long-term, and repeated human-animal interactions that occurred at particular times and places (e.g., the seasonal hunting of caprines and fallow deer at Ökuzini and just caprines at Karain B). It seems feasible that these interactions were central to human culture – in the form of songs, dance, and stories – that, together with the group's mobility, ensured knowledge of and relations with the environment were maintained (Ingold 2000: 56–7).

It is clear from the later phases at Ökuzini that human mobility gradually reduced as occupation became longer in duration, evidenced by faunal indicators of seasonality (Atici 2009: 34). The zooarchaeological data also demonstrate a steady increase in the range of species that were hunted, with fallow deer, roe deer, and wild boar becoming better represented through the chronological sequence. This move towards sedentism and the hunting of a wider range of prey, undertaken from a single settlement base, indicates a change in human-animal-landscape relationships that must have altered the way that people perceived their environment. Knowledge of the site's immediate surroundings would have intensified, allowing far deeper relationships with their locality but at the expense of other places that were previously part of the group's familial landscapes. As mobility reduced and people "lost touch" with areas beyond their day-to-day range, these more distant areas presumably became unfamiliar, perceived as the dangerous dwellings of ancestors and spirits (Ingold 2000: 43).

The emergence of sedentary farming communities can only have accelerated the contraction of landscape knowledge and engagement. To some extent this is reflected by the zooarchaeological data for the Near East and Mediterranean: surveys of faunal representation show a gradual drop-off in wild animal representation from the ninth millennium BCE, with wild animals becoming scarce in zooarchaeological assemblages from about 7500 BCE (Vigne and Helmer 2007: 34; Arbuckle 2012: 217). Certainly this is the case at Bademağacı Höyük, an early Neolithic to Bronze Age settlement located approximately 30 km northeast of, and in an similar environmental setting to, Ökuzini and Karain B. Table 1 shows that, in contrast to the high frequency of fallow deer at Ökuzini, *D. d. dama* remains constitute just 0.9% of the earliest Neolithic assemblage from Bademağacı. If it is accepted that zooarchaeological assemblages reflect human-animal-landscape interactions, the Epipaleolithic to Neolithic decline in wild animal representation can be taken as evidence for a fundamental change in human experience and environmental engagement. An increasing focus on domestic animals and landscapes created something new: the "wild," which now existed beyond the Neolithic settlements and their daily activities. de Cupere et al. (2008: 383) concluded that hunting played only a minor role in the subsistence of Bademağacı's occupants and that the deer were probably hunted locally on the plain surrounding the settlement. Recent carbon and nitrogen isotopic analyses of the fallow deer from Bademağacı ($n = 34$) may confirm localized hunting, the results being more tightly clustered (suggesting similarity of baseline environment) than has been observed for any other *D. d. dama* population analyzed to date (Sykes et al. 2011; Madgwick et al. in press).

The low frequencies of fallow deer (and other wild animals) in Neolithic assemblages should not, however, be equated with a lack of social importance. Indeed, as wild animals and their habitats became less familiar to the Neolithic populations, the significance of both may actually have increased. Within farming societies, hunting is usually about more than the acquisition of meat – it is a special activity, often a ritualized expression of identity (be it status, religious beliefs, ethnicity, gender), power, authority, or landownership (Helms 1993; Hamilakis 2003; Sykes 2007a). The value placed upon hunting derives from its unpredictability and danger, with hunters traveling beyond the comfort of their settlements into unknown landscapes to confront unknown beings. In her analysis of traditional societies, Helms (1993: 153–7, 211) demonstrated that, across cultures, geographical distance is equated to supernatural distance and that the hunters' ability to successfully negotiate "outer realms" is frequently regarded as a sign of shamanic status or supernatural authority. Given this association, together with the fact that hunting requires violent engagement with potentially dangerous wild animals, it is unsurprising that hunting skill is often deemed an important trait of male leadership in warrior societies (Cartmill 1993; Helms 1993; Hamilakis 2003; Sykes 2011: 336).

The possibility that there was an association between hunting and masculinity in Prehistoric Anatolia is perhaps discernible in the zooarchaeological record. Figure 3a shows clearly

Hunting and Hunting Landscapes, Fig. 3 (**a**) Plot of astragali measurements – greatest lateral length (*GLl*) against distal breadth (*Bd*) – for fallow deer from Anatolia. (**b**) Plot of astragali measurements – greatest lateral length (*GLl*) against distal breadth (*Bd*) – for fallow deer from mainland Greece

that fallow deer bucks were preferentially hunted at Bademağacı, the distribution of astragali measurements suggesting a male-female ratio of 4:1. Male fallow deer are also overwhelmingly predominant at Neolithic Fikirtepe (Turkey) where very few females are represented (see Fig. 3a; Boessneck and von den Dreisch 1979). From an economic perspective, these male-dominated assemblages could be interpreted as evidence for optimal foraging, the hunters targeting animals with larger carcass weight. However, given the considerable anthropological evidence for hunting communities, it seems more likely that these sex ratios reflect the role of hunting as an expression of masculinity: men deliberately seeking to confront the larger and more violent male of the species.

Under such circumstances, the role of dogs as hunting companions is more logical. Rather than representing a distraction, as was suggested for the Epipaleolithic period, dogs would have been valuable assets for macho-based hunting, offering both assistance in tracking quarry and companionship but also protection if needed. Work by Bartosiewicz (1990) has demonstrated a positive correlation between the frequencies of dog and wild animals in Neolithic assemblages from Europe and the Near East, suggesting that the two are directly associated. No such trend is apparent for Bademağacı, for although dogs are represented throughout the site's occupation, their frequency does not increase in parallel with the remains of wild animals: Table 1 shows that the representation of fallow deer at Bademağacı increases to over 2% from the ENII phase onwards. Several other Neolithic and Chalcolithic sites – notably Ilıpınar, Fikirtepe, Kumtepe, and Ulucak – demonstrate even greater frequencies of *D. d. dama* bones. Interestingly, this upsurge in fallow deer hunting corresponds with the period in which fallow deer began to be transported, by people, outside their natural range.

Hunting Landscapes of the Aegean: Diaspora of Fallow Deer and a Common Aristocratic Culture

Reviews by Yannouli and Trantalidou (1999) and Masseti (2002) highlight that dama remains have been identified in Neolithic assemblages from the islands of Rhodes, Crete, Chios, Lesbos, the Cyclades, and Sporades. Fallow deer are not part of these islands' native fauna and so must have been imported from Anatolia as part of the Aegean-wide trading/communication network that developed during the period (Masseti 2002: 163–4; Barker 2005).

According to Masseti (2002: 164) and Barker (2005), fallow deer were exported specifically for hunting purposes, and it seems likely that their transportation was accompanied by the

establishment of a common hunting culture across the Aegean. Certainly, a Neolithic to Early Bronze Age increase in wild animal representation has also been widely observed for mainland Greece (e.g., Hamilakis 2003), and research by Yannouli (1994) has highlighted that, for sites in Macedonia at least, this is coincident with the emergence of fallow-focused hunting. At Sitagroi, for instance, *dama* are very poorly represented in the earliest Neolithic levels (0.01–0.1%) but become the dominant cervid species at the advent of the Bronze Age, accounting for 1.6–2.2% of the mammalian assemblage (Table 1). Metrical analysis demonstrates that, as in Anatolia, hunting strategies were highly selective, with an overwhelming predominance of fallow deer bucks at both Sitagroi and Paradeisos (Fig. 3b). If, as has been argued above, male-dominated assemblages reflect social rather than economic concerns, this would seem to support Hamilakis's (2003: 242) argument that hunting was becoming an important arena for the negotiation of power and gender roles, in particular masculinity, associated with the rise of warrior identities. The hunting of fallow deer, a species that was beginning to unite distant parts of the Aegean, may have enhanced further the significance of the activity. By allowing hunters to engage in a common, yet simultaneously exotic, set of cultural practices, the participants became active members of a world beyond the local – a situation that would have allowed mental geographies to enlarge.

Bronze Age perceptions of hunting landscapes are difficult to fathom, but the introduction of horses must have transformed the way in which hunts were conducted and experienced: expeditions could now take place at speed with participants afforded a new vantage from their position within a chariot or on horseback. It is clear from iconographic evidence that both horses and hounds were important components of Bronze Age hunting, one of the earliest and most detailed depictions of this association coming from the LCI site of Ayia Irini (Kea). Here miniature friezes are painted on the walls of what is thought to be a large banqueting hall (Marinatos and Morgan 2005: 120). Horses and chariots are shown adjacent to scenes where a fallow deer being chased by a hunting dog and another where a male helmeted hunter is shown carrying a dead deer slung from a pole. The rest of the fresco appears to illustrate men carrying drinking paraphernalia and cooking over tripod cauldrons. The relationship between these different scenes has been interpreted as evidence that, in the Bronze Age period, hunting and feasting went hand-in-hand (Wright 2004: 169).

In terms of landscape, the majority of Ayia Irini's frescoes provide considerable details of the surrounding sea, coast, marsh, plants, rocks, and sky. The one exception is the hunting scene, which is set apart by its barrenness: the dog and deer are painted on a plain background of yellow ochre. Marinatos and Morgan (2005: 120) argue that this juxtaposition represents the remote landscape of the deer hunt, suggesting that it took place away from the settlement and beyond the vision of the eye. The naturalistic style of the deer's representation led Marinatos and Morgan (2005: 121) to speculate further about the season of the hunt. The deer is shown to have a penile brush distinctive of a buck, but the lack of antlers, which today are shed in April, together with the illustration of the animal's spotty summer coat indicates a May-to-October setting. Is it possible that male hunters of the Bronze Age chose the summer months to hunt in the sparse wilderness before returning to feast?

This is certainly the interpretation of Koehl (1986) whose integrated analysis of the highly decorated Chieftain Cup recovered from Agia Triada (Crete) enabled him to speculate that Minoan boys were required to undergo a maturation ritual whereby they spent 2 months hunting in the wilderness before their reintroduction to society as men. On their return the initiated youth would be rewarded with three gifts symbolic of their new warrior status and their induction to the adult world of religion and banqueting: weapons, a sacrificial ox for feasting, and a drinking cup (Barringer 2001: 13). Koehl (1986) argues that the Chieftain Cup represents all three gifts: its decoration showing both the awarding of arms to a young man and the skins of the sacrificed oxen, while the object itself represents the third gift of

the drinking vessel. Admittedly, this coming-of-age ritual is not documented until the fourth century BCE, but at this point, it was understood to be a long-standing ritual of Crete (Barringer 2001: 13), and the suggestion is not out of line with the iconographic evidence (Marinatos and Morgan 2005) or that from the zooarchaeological record. By example, Table 1 shows that hunting took place at Agia Triada, where fallow deer are the best-represented cervid and their frequency gradually increases through time, perhaps reflecting population growth following the species' introduction to the island.

Frescoes from Agia Triada suggest that the Bronze Age population viewed fallow deer as something other than just quarry: one fresco fragment appears to depict a woman leading two fallow deer to an altar (Yannouli and Trantalidou 1999: 279). The possibility that more complex relationships with fallow deer gradually began to emerge is perhaps indicated by the zooarchaeological record. Several sites in Anatolia (e.g., Troy I–III), Greece (Kastanas), and Crete (Chania) show high frequencies of fallow deer (Table 1); however, by contrast to the Neolithic and Early Bronze Age assemblages, metrical analysis indicates a more equal male-female ratio (Fig. 3a, b; Harris in press). This shift in hunting strategy may simply be a product of more intensive hunting, but it could equally suggest that across the Aegean, and at approximately the same time, the status and significance of fallow deer were diversifying – no longer was buck-hunting the sole focus of human-dama relationships. Credence is added to this suggestion by the Linear B tablets of Pylos which list different kinds of deer: those that are wild, those that are domestic, and those used in games or for sacrifices (Yannouli and Trantalidou 1999: 254). The possibility that some deer were being tamed or even maintained in parks (Hamilakis 2003: 344) would have created new kinds of landscapes where people, presumably the elite, could regard deer at close quarters. Indeed, it is possible that emparked deer were used in staged hunts as a demonstration of elite power and authority, as was common in contemporary Anatolia and Mesopotamia (Arbuckle 2012: 217).

The role of deer hunting as an ideological and power-generating resource is widely accepted for Mycenaean societies, where depictions of deer and hunting scenes are amongst the most common themes in iconography (Hamilakis 2003: 243–4; Wright 2004: 160). The themes are very similar to those of Minoan iconography: the frescoes from Mycenaean Pylos (hall 46) are very reminiscent of those from Ayia Irini, again showing men and dogs hunting deer but also carrying tripods for cooking meat (Wright 2004: 160). The idea that hunting and feasting continued to be closely associated and central to elite culture finds support from the zooarchaeological record: several sizeable fallow deer assemblages from Chania (Crete) were recovered from large pits that also contained quantities of dining and drinking vessels, typical of feasting deposits (Table 1; Harris in press).

The zooarchaeological record for Crete suggests that the end of the Bronze Age brought a decline in fallow deer hunting: according to Table 1, *D. d. dama* frequencies drop off through the course of the Iron Age. The only site where they are well represented is Prinas, but here it should be noted that all the specimens came from temple contexts (Wilkens 2003: 86). A similar situation is true for the Iron Age remains from Knossos, which were recovered from the sanctuary of Demeter (Table 1).

Cultic significance may explain why fallow deer persist as a common iconographic motif, Yannouli and Trantalidou's (1999) detailed review demonstrating their continued representation through the Iron Age, Archaic, Classical, and Hellenistic periods. Barringer's (2001) study of hunting in Archaic and Classical Greece also highlights fallow deer as a frequently depicted quarry on Attic vases. She notes a strong association between the themes of hunting and warfare, a connection that apparently intensified around 520–510 BCE when a number of changes occur in both the design and form of the vessels. First, there is a shift in the ceramic forms on which hunting is depicted, the imagery becoming restricted almost exclusively to cups and other drinking paraphernalia typical of the aristocratic male symposium (Barringer 2001: 16). In terms of design, the traditional hunting weapons – spears

and tridents – are replaced by depictions of swords, weapons less conducive to hunting but typical of the period's military gear (Barringer 2001: 19). At approximately the same time, illustrations of communal hunts become less frequent, and the hunters appear more heroic in their stance and costumes (Barringer 2001: 32). Depictions of landscape also become more prominent, which Barringer (2001: 18) suggests may have been designed to emphasize the wild location of the hunt. Taking all these changes together, Barringer (2001: 16) argues that they reflect the aristocracy's attempts to deploy the symbolism of hunting and heroism in order to maintain power and social control at precisely the point when both were diminishing with the advent of democracy.

While fallow deer hunting continued to be aligned with masculinity and warfare – a theme reflected in the literature of Xenophon, Aristotle, and Plato (Barringer 2001: 11) – the Archaic and Classical period also saw fallow deer coming to represent women and children. This presumably resulted from the fallow deer's growing association with Artemis, the goddess of hunting, whose identity developed through the syncretism of Anatolian and Greek antecedents (Fischer-Hansen and Poulsen 2009: 12). This well-known connection between fallow deer and Artemis is often expressed artistically from the Archaic periods onwards (Yannouli and Trantalidou 1999: 258), and it is also from this point that votive deposits of dama bones are more common within cultic contexts. For instance, approximately 60 fallow deer astragali were recovered from the Korykeion Antron near Delphi, a cave associated with the cult of nymphs who were thought to protect children. A further 11 dama astragali were recovered from the Kabireion sanctuary at Thebes, and interestingly, metrical analysis indicates that all are from female individuals (see Fig. 3b). This is an important find suggesting that, by contrast to the buck-hunting of the Neolithic and Early Bronze Age, female deer were specifically targeted, perhaps with these particular rituals in mind.

If not already common in Anatolia, the concept of hunting fallow deer for cultic purposes may have been exported back to the species' homeland during the Hellenistic period. Table 1 shows that exceptionally high frequencies of fallow deer remains were recovered from the Greek phase of Troy (VIII) and, according to Fabiš (2003: 267), the majority came from sanctuary contexts. Again, Fabiš (2003: 274) stresses the links between fallow deer and Artemis, citing examples of iconographic evidence from the region that confirm the association. Given that the cult of Artemis was one of the most popular and widely established in antiquity (Fischer-Hansen and Poulsen 2009), it seems plausible that this was the very motivation for the human-assisted spread of fallow deer across the Roman Empire, an issue to which we now turn.

Roman Europe

The association of fallow deer with Artemis, or rather her later incarnation as the Roman goddess Diana, has been explored in depth by not only Yannouli and Trantalidou (1999) but also Reinken (1997). It is clear that the goddess and fallow deer are intimately linked; however, this relationship has actually obscured whether the cult was responsible for the spread of the species. This is because body parts, rather than living deer, appear to have been transported over considerable distances for use in ritual, magic, and medicine. For instance, fallow deer foot bones have been recovered from the Temple of Diana in Augst (Switzerland), and isotopic analyses of shed antlers and foot bones from a variety of north European contexts have returned values that indicate these body parts were imported from the Mediterranean or Anatolia (Madgwick et al. in press). Nevertheless, isotopic studies have also confirmed that the Roman period saw breeding populations of fallow deer established across the western Mediterranean and as far north as England. In the majority of cases and following Neolithic and Bronze Ages practices, the deer were introduced to islands: notably Sicily, the Balearics, and the Isle of Thanet, located in the English Channel (Masseti 2002; Sykes et al. 2011). These sea-bounded areas would have served as natural game reserves, large enough for the deer to roam free and be hunted as "wild" animals, as they were on Rhodes and Crete. Iconographic representations from the famous fourth-

century mosaics of Piazza Armerina (Sicily) depict wide-ranging hunts with deer being driven into nets by hunters on horseback (Dunbabin 2004: 146). The villa's *Mosaic of the Small Hunt* combines this imagery with scenes of votive offerings to Diana but also feasting, whereby the hunters picnic on the products of the hunt. According to Dunbabin (2004: 146), hunting scenes emerged as a popular motif from the third century onwards, when the possession of productive estates, hounds, horses, and leisure time were the defining traits of elite identity – hunting serving as the nexus through which all could be communicated.

The Roman period saw, therefore, not only the amalgamation of landownership, status, and hunting but also the use of this tripartite as an important motif in visual culture. It is perhaps no coincidence, then, that the first unambiguous evidence for the establishment of private game parks, known as *vivaria*, also dates to the Roman period (Sykes 2010).

In Italy, there is some suggestion that such a park may have been constructed at the grand villa of Settefinestre, built around 75 BCE near the costal colony of Cosa (Carandini 1985). The villa was set in a large estate that included orchards and a variety of walled gardens, spaces that could certainly have housed the fallow deer whose remains were recovered from the site (Table 1). More definitive evidence for the establishment of game parks is found at another lavish villa, Fishbourne Palace on the south coast of England. This site has produced the largest collection of *D. d. dama* remains from Roman England, but as Table 1 highlights, their remains are still very rare ($n = 38$). The exotic status of these animals was confirmed through strontium isotope analyses (a geochemical provenancing technique) of the available *D. d. dama* teeth from Fishbourne. This identified the presence of an individual that was imported to the site as a juvenile, perhaps a gift from across the empire; however, another deer was shown to have been born and raised at the palace (Sykes et al. 2006). More recent studies of bone chemistry (carbon and nitrogen isotope analyses) to examine the deer's diet have highlighted that most of the animals likely grazed close to the palace, perhaps within the formal gardens, but others must have been managed in the more "natural" southern garden, an area that gave the deer access to the nearby salt marsh, indicated by exceptionally high nitrogen values (Madgwick et al. in press).

The management of deer within enclosed areas marks a transition in the *dama*-human relationship, to a situation more akin to domestication. The paradoxical nature of parks, landscapes in which wild animals were maintained as domesticates, reveals something of the period's cultural ideology. *Vivaria* represent a landscape-based statement of human dominion over nature, reflecting the mind-set of the Romans who saw it as their spiritual duty to bring the wilderness to order (Cartmill 1993: 52). This is a key point which would seem to separate the Roman worldview from that of the preceding Iron Age, when no such concept of dominion existed. Indeed, it would seem that in the Iron Age, the wilderness was viewed a sacred space with cultural taboos placed on the hunting, trapping, and harvesting of all wild resources (Sykes 2010: 23–4).

Why such differences existed between Iron Age and Roman England can, most probably, be linked to inter-period variations in mobility, long-distance trade, and geographical knowledge. By contrast to the Roman period, Iron Age England was parochial and insular, and the areas beyond settlements seemingly represented the unknown outer realm, where votive deposits, sacrifices, and funerary rituals took place (Sykes 2010: 24). Increasing trade with the continent during the Late Iron Age and Roman period, followed by the arrival of new peoples and things, would have blown apart existing geographical knowledge, the "exotic" replacing the wilderness as the new outer realm. It is probably for this reason that, in the Roman period, exotic goods become common votive offerings whereas wild animals appear to lose their sacred status; their remains are found increasingly in domestic food deposits, particularly from elite sites (Sykes 2010: 28).

The hunting culture brought to England by the Romans was not to last however. Withdrawal of the empire in CE 410 and the associated decline in

international trade saw a reversion to Iron Age attitudes to hunting and the wilderness.

The Hunting Landscapes of Medieval England

The Early Anglo-Saxon period (fifth–seventh century CE) saw the return of taboos over the exploitation of wild resources with little evidence for hunting (Sykes 2011: 331). This is not to suggest that belief systems were identical to those of the Iron Age, as the avoidance of wild resources may reflect a new perception that the wilderness was a scary, rather than sacred place, inhabited by supernatural beings and monsters such as *Beowulf*'s Grendel. For whatever reason hunting declined, all the evidence, including new genetic data, suggests that fallow deer also went extinct in Anglo-Saxon England (Sykes and Carden 2011).

After a hiatus of several centuries, hunting gradually began to reemerge as a trait of elite male identity (Sykes 2011: 336). Evidence from documents, place names, and the zooarchaeological record indicates that woodland areas were increasingly set aside as private hunting reserves. It is uncertain whether these landscapes were enclosed by ditches or fences, but structures known as *haga* or *hai* were erected to ensnare deer, particularly roe deer, which were driven into them by trained hunting dogs and then dispatched with swords and knives (Sykes 2011: 341).

There is some evidence to suggest that Saxon hunting also took place on horseback (Sykes 2011: 341), although this form of long-distance hunting became common only after the Norman conquest of 1066, when the victorious Normans utilized hunting as an important mechanism for displaying their martial supremacy and control over the defeated Saxon population (Sykes 2007a: 96–7). Zooarchaeological evidence confirms that frequencies of wild animals increase dramatically on elite sites dating to the post-conquest period to levels far higher than was seen in the Roman period (Sykes 2007a: 65). Low-status sites demonstrate no such increase, a fact that must be associated with the introduction of new hunting laws and landscapes – forests, chases, and parks – that restricted hunting to the monarchy and aristocracy (Sykes 2007a). Forests were not necessarily densely wooded areas, as might be imagined, but rather legal spaces that were superimposed on top of the existing domestic landscape. Both forests and chases were unenclosed areas where the elite asserted their hunting rights over common waste and land owned by other people. As such, these hunting landscapes were unprecedented; for although landownership and hunting were conflated during the Roman period, this was not in any legal sense – the lower classes were still entitled to hunt. By forcibly restricting hunting to the elite, the Normans overturned the very "chain of being" central to Christian thought, placing the rights of wild animals and their habitats above those of the peasants and their fields, who were relegated down the chain to the lowly level of domestic (Sykes 2007b: 97).

The (re)introduction of parks to England imposed not only legal but also physical barriers to exclude the lower social echelons from hunting. Again, as in the Roman period, fallow deer were directly responsible for the reappearance of this new landscape, as is clear when the frequencies of parks and fallow deer are compared. The Domesday Survey of CE 1086 recorded just over 30 parks in England, but by CE 1300, this number had risen over 3000; the zooarchaeological representation of fallow deer grew in parallel, Table 1 showing low numbers in the earliest Norman contexts (e.g., 0.8% from eleventh-century Carisbrooke Castle, Isle of Wight) but large quantities on later medieval sites (e.g., 28% from fourteenth-century Okehampton Castle, Devon). Current evidence suggests that the inspiration for both parks and the fallow deer that stocked them came from Sicily, another island conquered by the Normans in CE 1060. At this point, Sicily had a preexisting culture of pleasure parks, developed while the island was under Arabic influence (Sykes 2007a: 74, 2007b: 59). It is reasonable to assume that the culture contact between two Norman kingdoms of England and Sicily encouraged the importation of parks and *D. d. dama* to Britain. However, it is important to recognize that the character of the earliest Norman parks would have been very

different to those of the later medieval period. For the first few decades after their introduction, fallow deer would have been a great rarity to be observed and admired rather than chased and eaten. Presumably many of the early "parks" actually functioned as menageries, such as Henry I's park at Woodstock (Oxfordshire) that was said to contain all manner of exotic animals gifted by members of the foreign elite as a symbol of political allegiance (Sykes 2007b: 59).

As fallow deer stock grew, so too did the size of some parks, particularly those in royal possession. These large areas could feasibly have supported a hunt on horseback, similar in form to those undertaken in unbounded landscape. That said, the majority of parks were far smaller, typically 100–300 acres, which would have dramatically limited the hunting experience. Many of these small parks were not only too small for full-scale hunting, but they were also of an inadequate size to support their stock: a plethora of medieval records detail the starvation of park deer (Birrell 1992). Lack of available nutrition may account for the significant size reduction seen for medieval fallow deer (compare Fig. 4 with Fig. 3a, b). Alternatively, this could equally reflect genetic change brought about through controlled breeding, as it is in the medieval period that we see the first iconographic evidence for coat-color variation (notably black and white fallow deer) which is usually a trait of domesticates (Masseti 2002: 140).

The fact that parks were stocked with captive, diminutive, selectively bred fallow deer has raised debate about the purpose and function of parks – were they really arenas for masculine hunting, status symbols of the landed elite, or simply game larders where venison could be stored on the hoof? In all probability parks served to provide all these social and economic purposes; however, increasingly, it is being recognized that parks were important hunting landscapes but for elite women, rather than men (Sykes 2007b: 54).

The level of female involvement in medieval hunting has been the subject of some controversy, with debate surrounding the medieval iconography that depicts women hunting. Some of the images are clearly jokes, ridiculing the idea that women could possibly take center stage in deer hunting, but others appear more realistic. In particular there are a number of manuscript illuminations that show women shooting arrows at deer (Sykes 2007b). Significantly, the cervid depicted in association with women is almost invariably fallow deer, identifiable by their distinctive spotty coat, palmate antlers, and prominent penile

Hunting and Hunting Landscapes, Fig. 4 Plot of astragali measurements – greatest lateral length (*GLl*) against distal breadth (*Bd*) – for fallow deer from medieval England

"brush." While it is unwise to read medieval images at such a superficial level, it is interesting that women are so clearly associated with the species that was maintained within parks. Irrefutable evidence that parks were female-hunting landscapes can be found in the historical record. For instance, in John Coke's *Debate Between the Heralds* (cited in Cummins 1988: 7), the English herald states:

> we have also small parkes made onely for the pleasure of ladyes and gentylwomen, to shote with the longe bowe, and kyll the sayd beastes.

That parks were hunting spaces for elite women is perhaps unsurprising at a time when hunting was an important part of popular culture but also when courtly societies emphasized the seclusion of young aristocratic women. In order to ensure female chastity and purity, so essential to patrimony, their mobility and visibility were restricted in public arenas – parish churches, banquets, and even travel between households. It is highly unlikely that young women would have been encouraged to hunt in the wider landscape; more probable, it was within the confines of the park that ladies gained an education in hunting without fear of observation (Sykes 2007b: 54).

The situation in medieval England could not be further removed from that of Prehistoric Anatolia, but the contrast between the two exemplifies how human-animal-landscape interactions offer insights into the cultures under examination.

Discussion and Conclusion

From Epipaleolithic Anatolia, when the concept of "wild" did not exist because it was *all* that existed, to medieval England, where semi-domestic deer were housed in equally tame parks, the history of fallow deer and the landscapes in which they were hunted can be viewed as a record of social and cultural change. The journey between these two extremes was not, however, a linear evolution. It has been argued that the dynamics and social significance of hunting are connected to cultural worldview and wider attitudes to nature, which in turn correspond to the ebb and flow of human movement and/or long-distance contact.

It can be no coincidence that periods characterized by insular sedentism – notably the Iron Age and Anglo-Saxon periods of England – indicate an avoidance of wild animals and the "wilderness," with no obvious attempts to control or own elements of the natural world through the movement of exotica or the creation of parks. This contrasts dramatically with those periods characterized by movement, trade, or diaspora – the Epipaleolithic of Anatolia, the Neolithic and Bronze Age of the Aegean, or the Roman and Norman Empires – which are also those characterized by hunting cultures, many of which were responsible for the translocation of fallow deer. In these periods, mental geographies were broad and the wilderness was conceptualized as something to be engaged with, either as a statement of familiarity (e.g., for hunter-gatherers of Okuzini and Karain B) or to emphasize power, authority, and, particularly for the two Empires, control. However, even in periods where the prevailing worldview was one of human dominion over nature, wild animals were not perceived as inferior to people, far from it. The status attributed to hunting derived from the fact that the quarry and the landscape in which they dwelt were unpredictable and would not necessarily yield to an unworthy hunter. That respectfulness was key is reflected by the votive offerings of fallow deer and other wild animals, noted across the Bronze Age and later Aegean as well as the Roman Empire. The association between wild animals and ancient deities, most notably Artemis – goddess of wild animals – is in many respects similar to the "animal masters" of many modern hunter-gatherer groups; indeed, the ancestry of the goddess Artemis can most likely be traced back to the beliefs of Paleolithic hunter-gatherers (see Fischer-Hansen and Poulsen 2009: 12).

Remarkable continuity is apparent in the cross-cultural associations between hunting, masculinity, and warfare. The relationship becomes evident for the first time during the Neolithic and Bronze Age of both Anatolia and the Aegean, but the same concepts are then found recycled in Archaic, Classical, and Hellenistic Greece, reemerging after a hiatus in the later Roman and medieval periods. Contemporary

literature and, in particular, iconography highlight that the choice of hunting landscape is an integral part of this association: from the Minoan frescoes of Ayia Irini, through the representation of deer hunting on fifth-century BCE Attic pottery, to the fourth-century mosaics of Piazza Armerina (Sicily), all stress the "wildness" of the hunting landscape, setting it in opposition to, and away from, that of the domestic world. As much as scholars have critiqued the utility of binary oppositions (e.g., male-female, wild-domestic, outside-inside), they appear highly relevant in the context of hunting. Indeed, for Bronze Age and later Greek societies, there is some suggestion that it was only through spending time hunting, away from the domestic world, that boys were transformed into men capable of bearing arms. Here the killing of wild animals is clearly important, but the vital element of this rite of passage is the "outside" setting of the hunting landscape.

Confirmation of these binary oppositions is found by examining the evidence for later medieval England. As soon as fallow deer were enclosed within parks, they were no longer fitting quarry for men who continued to hunt "real" wild animals (red deer and roe deer) across unbounded forests and chases – there is little medieval iconography depicting aristocratic men hunting fallow deer, and literary references are also scarce (Birrell 1992: 122; Sykes 2007b: 52). Instead, parks with their domestic inhabitants became important hunting landscapes for aristocratic women. Within the confines of the pale, young ladies were able to ape Artemis and Diana, the virginal goddesses with whom fallow deer had become so closely associated.

The link with Artemis, in her various incarnations, seems to have been an important driving force for the diffusion of fallow deer from Anatolia. Paradoxically, however, anthropogenic transportation and emparkment of these deer gradually destroyed the very human-animal-landscape relationship that was initially sought for replication – the wild was tamed and the sacred became secular, a sad fall from grace for such a beautiful and culturally important species.

Hydraulic Engineering: Geoarchaeology

T. J. Wilkinson
Department of Archaeology, Durham University, Durham, UK

Introduction

Water is a fundamental structuring agent in the landscape, but unfortunately, the geoarchaeology of hydraulic installations and their deposits is an under-investigated topic, little mentioned in standard geoarchaeological texts. This entry summarizes key diagnostic features of water extraction and delivery systems, before providing examples of the resultant deposits and soils. In order to fully understand how water supply systems and their associated deposits developed, it is necessary to investigate them through long periods of time, not simply according to the "time slices" that are frequently the norm in academia. We are then able to tackle the long-term history and "evolution" of water systems as well as to relate them to the duration of sedimentary deposits associated with them.

The following approaches contextualize the geoarchaeology of hydraulic engineering:

(a) The geomorphological context which frames the development of irrigation systems. This includes riverine floodplains, alluvial fans, the terrain below or downstream of springs, areas of high water tables, enclosed basins, valley slopes, and so on. Not only does this "framing geoarchaeology" provide the physical context for hydraulic installations, it also supplies the opportunities for communities to develop different types of water supply systems as well as creating hazards that initiate episodic change such as floods, crevasse splays, and avulsions.

(b) The resultant deposits and soils. These include the deposits (or lack of them) which derive from the sediments transported and deposited by various water supply systems. On the one hand, these consist of sediments that clog irrigation systems (but which also deliver nutrients for agriculture), as well as deposits that are deliberately built up to form the medium for cultivation (e.g., terraces and check dams). In addition, deposits include chemical precipitates associated with water supply, particularly carbonate deposits (travertines) and salts.

Because human actions underpin hydraulic engineering works, the nature of these actions and the associated social processes must be considered as well. By no means all hydraulic works are planned or deliberately engineered; many

remarkably large systems began as small-scale systems and then were increased in size by gradual additions (Denevan 2001: 148), in which case it would have been necessary to increase the flow capacity.

Two broad levels of organizational scale are recognizable:

1. Those systems that show evidence for "bottom-up" development and which grew incrementally as a result of the actions of communities who built on preexisting natural circumstances to form initially small-scale systems. These organic systems can be argued to develop by way of niche construction as argued by evolutionary biologists and anthropologists (see below).
2. On the other hand top-down management tends to be associated with systems that are larger in scale but were not necessarily developed in one operation. They were often planned and "engineered" and their administration was partially controlled by a king or imperial ruler. Nevertheless, there is no direct relationship between authority, state formation, and the scale of irrigation systems. However, in the Middle East, with the expansion of the later empires, dating from the rise of the Assyrians around 1000 BCE, we see the proliferation of large-scale and frequently engineered systems that represent classic examples of top-down systems.

Definition

This entry primarily focuses upon water supply features: canals and other water channels, dams, terrace walls, wells, and reservoirs as well as their associated deposits and soils. Before describing these, however, it is necessary to define the geoarchaeological signatures of the features themselves as well as their state of survival in the landscape.

Diagnostic Features of Canals and Water Supply Systems

Figure 1 shows some basic water supply features in the Middle East together with their associated deposits. Although the functional part of such installations is frequently the void, either the canal that conducted the water flow or the well or qanat shaft that accessed the water table, the upcast deposits are frequently the most informative deposits, especially when sampling schemes need to be designed (Fish 1994: 57–61). Residual deposits were often dumped in sequence according to the history of excavation. Consequently those soils removed first were dumped initially upon a buried soil and were then followed by the products of the different geological strata encountered as the feature was dug to deeper levels. Finally, in the case of canals that transported a significant sediment load, the primary deposits were followed by secondary accumulations of silt, clay, and organic materials cleaned out of the canal itself. Very similar types of sequences can be recognized in both Old and New World canal deposits (Fish 1994: Fig. 3.2; Wilkinson 2003: 49).

Remote sensing methods are an indispensible tool for the geoarchaeological analysis of hydraulic systems especially for the recognition of canal spoil banks. Satellite remote sensing is becoming increasingly useful as high-resolution and multispectral images are becoming more cost-effective and archive images such as those of the CORONA series dating from the 1960s and 1970s become available. In addition, Shuttle Radar Topographic Mission (SRTM) data have been used to graphically illustrate a range of water supply networks including levees of canals and river channels that bifurcate across the seemingly flat plains of southern Mesopotamia.

A major challenge presented by early hydraulic networks is how to establish their date of use. Channel floor deposits can be of help, especially if they contain molluscs, bones, or charcoal that can be dated radiometrically, but because canals are frequently cleaned out, the channel deposits might only be the latest members in a long history of use (Purdue et al. 2010).

In lowlands, canals can form the most imposing features in the landscape, but their sheer scale can give a misleading impression of the size of the actual canal contained between the spoil banks. This is illustrated by a sketch section across a

Hydraulic Engineering: Geoarchaeology, Fig. 1 Schematic sections of various types of water installation in the Middle East: (**a**) water hole, (*1*) fill, (*2*) water table (chemically reduced soil); (**b**) well, (*1*) fill within shaft, (*2*) water table within gravel (chemically reduced), (*3*) gravel, (*4*) initial gravel upcast, (*5*) clean out silts, (*6*) wind-blown sand, (*7*) buried soil, (*8*) cone of collapse; (**c**) masonry open channel, (*1*) waterproof plaster, (*2*) masonry with large cobbles, (*3*) buried soil; (**d**) earthen canal with spoil banks, (*1*) sand and gravel channel fill, (*2*) subsequent fills, (*3*) primary spoil from initial excavation, (*4*) secondary silt from cleaning out, (*5*) buried soil; (**e**) canal with spoil banks deflated, (*1*) fill, (*2*) location of deflated spoil banks; (**f**) terraced field, (*1*) terrace wall, (*2*) wedge of stones for subsoil drainage, (*3*) accumulated terrace deposits, (*4*) weak palaeosol, (*5*) pre-terrace palaeosol. (Modified from Wilkinson 2003: Fig. 4.1)

Hydraulic Engineering: Geoarchaeology, Fig. 2 Sketch section of a canal in NE Iran showing how the depth of the canal influences the scale of the canal cross section

canal in NE Iran (Fig. 2). The 50 m wide canal trace gives the impression that the canal itself was equally large. However, because we know that in the area in question the water supply (the Gorgan River) was some 10–12 m below ground level, it is clear that a large quantity of upcast would have been created to enable the canal to attain the water source at river level. In other words, the scale of the upcast is a product of the dimensions of the canal channel *and* the depth of the water source. In

Hydraulic Engineering: Geoarchaeology, Fig. 3 Canal trace at Pamukkale Turkey showing thick accumulations of calcium carbonate

the case of this particular canal (Fig. 2), the volume of upcast and the width of the canal at the surface diminished downstream as the canal channel approached the ground surface in the vicinity of the fields.

An important contextual feature of canals, dams, reservoirs, cisterns, and tanks is the presence of associated and functionally related installations such as kilns for the burning of lime used in the manufacture of cements and plasters. Not only are kilns of intrinsic technological interest, they also provide valuable materials in the form of charcoal or fired bricks that can be dated, by radiocarbon, OSL (Optically Stimulated Luminescence), or thermoluminescence. Such associational dates can be exceedingly valuable because they provide a date estimate for the initial phase of construction of the hydraulic feature or at least the first use of plaster and cement.

In addition to being recognized by their upcast deposits, some canals are evident as fossilized traces, the best examples being those of the Tehuacán Valley of Mexico which were fed by calcium carbonate-enriched spring waters. As a result of their resistance to erosion, these "travertine encrusted" canals stand up to 2 m above the surrounding ground surface (Doolittle 1990: 58–59). In the Middle East a remarkable series of such travertine encrusted canals, probably of Byzantine date, occur near Pamukkale in Turkey (Fig. 3). Although such features are not common, when they do occur, they can then be dated by Uranium series or radiocarbon methods.

The Geoarchaeology of Preservation

As a result of their location near to water courses, especially major rivers, engineered hydraulic systems are vulnerable to destruction or burial.

Canals that take their flow from fluvially dynamic rivers such as the Gorgan River in NE Iran (Fig. 4) are particularly vulnerable to riverine erosion, and the assessment of the relative completeness of canals and conduits is a major challenge for geoarchaeologists. In fact, in the Middle East complete water supply systems are relatively scarce, one of the rare examples known to the writer being the Abbasid period (c. ninth century CE) open channel *falaj* at Arja in northern Oman. This shows the complete sequence from the water capture area within a perennial wadi, the transport section downstream, as well as the irrigated fields and even a water mill (Wilkinson 2003: Fig. 9.12). In contrast, most water supply conduits leading to early Islamic Siraf on the Iranian coast have been expunged by the erosive rivers that surge down from the neighboring Zagros Mountains.

Despite their vulnerability to erosion, if water systems were constructed in relatively stable arid landscapes, specific installations can remain for long periods. Particular good examples are the

Hydraulic Engineering: Geoarchaeology, Fig. 4 CORONA image of the same canal system as illustrated in Fig. 2. Note the spoil banks to north and south and the large chunks of canal eroded by the meandering Gorgan River. (CORONA image courtesy of US Geological Survey)

water installations in the Wadi Ghuweir in the Jordanian desert where the combination of geomorphological stability and the absence of subsequent phases of cultural activity has left these PPNB water-gathering bunds relatively intact over some 10,000 years (Fujii 2011).

Historical Background

Geoarchaeological studies of ancient irrigation deposits extend back well before the term geoarchaeology was coined. For example, the classic studies of southern Arabian irrigated landscapes by Caton-Thompson and Gardner (1939) and Bowen (1958) provided a firm foundation for later studies. For Mesopotamia, the volume *Soils and Soil Conditions in Iraq* by the Dutch soil scientist, Peter Buringh (1960), went well beyond the cover title to provide insights into irrigated agriculture and the physical and cultural landscape which remain relevant today. Particularly important for an understanding of anthropomorphic soils of Central Asia are Soviet-era studies which were being published as early as the 1930s (Kovda and Lobova 1968). These monographs are not simply of historical interest, rather they demonstrate how thorough empirical studies of soil archives can provide significant insights into the long-term development of anthropomorphic soils. In the New World, although studies of early terraced fields extend back to the article by Cook published in the National Geographic in 1916, geoarchaeological studies of hydraulic landscapes and their deposits really picked up speed from around 1961 (Denevan 2001: 4–9).

Key Issues

Whereas, geoarchaeology conventionally concerns itself with geological applications to archaeological questions, the analysis of ancient hydraulic installations necessitates the inclusion of human agencies and community actions. Specifically, the management and development of water supply systems relates to the scale of the communities using or administering the systems, which, in turn, influences the scale of the installations as well as their deposits (although not necessarily in a linear way). In contrast to the earlier models of Wittfogel which see major hydraulic schemes as being a driving force behind early state development, many archaeologists now

consider small-scale actions by household size groups to be fundamental to hydraulic and other landscapes (Erickson 2006). This bottom-up perspective may encompass concepts such as "human niche construction" which provide a useful way of viewing the development of early small-scale water management systems.

This set of concepts, which developed out of evolutionary biology, incorporates the capacity of organisms including humans to modify their environment (e.g., via irrigation systems in Bali) in such a way as to influence their own evolution (Lansing and Fox 2011). This is illustrated for southern Mesopotamia where Buringh (1960) has suggested that by taking advantage of breaks in the banks of river levees, prehistoric communities manipulated the overflow waters that created crevasse splays so as to provide water for small irrigated gardens. These small-scale channels and patches became scaled up to eventually form much larger patterns of "herringbone" irrigation canals capable of supporting much larger populations than the original riverine environment.

Similarly, the point where rivers flowed out of mountains to preferentially deposit their sediments upon alluvial fans provided an ideal location for early prehistoric settlement. However, such situations, as described by the prehistorian Andrew Sherratt, could also result in the burial of both irrigated fields and associated occupation sites. Consequently, where human settlements developed in locations ideal for both irrigation and sedimentation, the landscapes can be referred to as "self-consuming."

In the Middle East, the growth of archaeological sites in areas of coalescing alluvial fans has probably severely retarded our understanding of the development of early irrigation settlements and such sites are relatively scarce. However, at Dar Khazineh and related sites in Khuzestan, SW Iran, small Late Susiana sites (c. 4800–4300 BCE) have been unveiled by intensive gully erosion from beneath a thick stratum of overlying sediments washed from the Zagros foothills. These investigations suggest that an unknown number of small agro-pastoral sites probably reliant on flood-recession cultivation lie buried within this sedimentary cover (Alizadeh et al. 2004).

Alternatively, where Hohokam settlements (CE 300 and 1500) developed on the alluvial piedmont zone (*bajadas*) of the Tucson basin of Arizona, they are much more visible. These sites, which occur at "gully-mouth fans" on *bajadas*, occur in analogous locations to Ak-Chin settlements farmed by historic Hopi communities (Waters 1992: 171–175). But because the Hohokam farmers located their settlements in areas suited to floodwater farming, their settlements also became buried as the gullies shifted position. In other words, in very different parts of the world and at different dates, very similar locations were selected for settlement and agriculture. However, the preservation of much larger numbers of Hohokam settlements in the SW USA has major implications for the development and demography of prehistoric settlement elsewhere. The comparative study of settlement in self-consuming landscapes is therefore an important priority for geoarchaeological research.

In the Yemeni highlands, where mountain valleys exhibited hundreds of walls and other built structures designed to intercept, redirect, and collect water downstream, long-term aggradation has been amplified by such programs of sediment interventions. For example, at Sedd Adhra 'ah, near Dhamar, some 6 m of anthropogenic sediments have buried a small check dam (dated by C-14 to c. 3000 BCE) and were later followed by sediments accumulated behind a major relict dam some 1,500–2,000 years old (Figs. 5 and 6). This sequence demonstrates how small-scale features eventually "scale up" to be succeeded by larger hydraulic features that reinforce earlier patterns of aggradation as well as how the cultural and sedimentary records coevolve in such deeply cultured landscapes (Wilkinson 2003).

On the other hand, engineered systems, often but not necessarily constructed by state-level rulers, can result in the construction of large-scale canal networks such as the Sasanian Nahrawan canal (Iraq: Adams 1965) or the Chicama-Moche inter-valley canal, constructed by the Chimú state (Peru: Denevan 2001: 152–157). Similarly, their deposits can be large in scale as well: for example, the cross profile of the Nahrawan canal is evident on SRTM

Hydraulic Engineering: Geoarchaeology, Fig. 5 Long section through a deep sequence of mainly anthropogenic fills and soils. Sedd Adhra 'ah, Yemen

Hydraulic Engineering: Geoarchaeology, Fig. 6 Detail of the valley floor check dam at the SE end of the Sedd Adhra 'ah sequence being cleaned for soil micromorphological samples

topographic images (Hritz 2010). However, in this case radar images distinguish several features: a broad levee perhaps of a preexisting river, which appears to have been taken advantage of by the canal engineers to form the foundation for the canal; a second more modest levee resulting from the canal itself; and third smaller distribution canals. Such top-down systems appear to be more amenable for satellite image analysis than those of smaller scale.

Where such large-scale canal networks derived their water from sediment-rich rivers, they create irrigated soils and associated deposits that blanketed virtually the entire landscape. These accumulations are well defined on soil maps, such as the FAO soil map of Khuzestan, Iran, where the surveyors distinguished between landscapes with "thick," "thin," or "absent" irrigation cover. Such maps are of immense value in identifying areas where archaeological sites may be obscured from view or as a starting point for geoarchaeological investigations.

Sediments and Soils Derived from Riverine Irrigation

Engineered hydraulic systems, be they large or small scale, play a fundamental role in sediment delivery, specifically by acting as huge sediment traps. However, the amount of sediment trapped depends upon catchment geology, land cover, and vegetation, as well as the nature of the water source. Whereas runoff systems or canals supplied by turbid rivers can be associated with significant long-term aggradation, hydraulic systems fed by springs or groundwater exhibit low sediment loads and limited aggradation but can be associated with significant amounts of chemical precipitates.

Irrigation-induced sedimentation is well known from southern Arabia with Marib (Yemen) supplying the best example. There, highly turbid waters diverted from the seasonal floods (*sayl*) of Wadi Dhanah by the first millennium BCE Marib Dam have created accumulations of up to 30 m of irrigation silts which extend over between 8,000 and 9,600 ha (Hehmeyer 1989). These deposits, which accumulated between 2000 BCE and 1000 CE, provide sedimentary archives containing evidence for the associated land use, including root casts of plants (probably date palms), circular impressions of bowls of fruit trees, as well as casts of fine root hairs of garden crops, cereals, and fodder plants (Hehmeyer 1989: 41). A characteristic feature of these irrigation silts is their distinctive rectilinear gullies eroded along less-resistant sand-filled irrigation channels which define the pattern of relict fields (Fig. 7).

Even more extensive spreads of relict irrigated soils cover most of the Mesopotamian plains in southern Iraq, but lacking the rectilinear erosion patterns, these are much more difficult to recognize. These riverine cultural landscapes form a complex mosaic of river/canal levees, levee slopes, and intervening flood basins or intermittent marshes (Buringh 1960).

Altogether, southern Mesopotamian landscapes result from both cultural and physical processes, which contribute to the coevolution of human practices of irrigation in association with anastomising river networks. So intimate is the connection between the human and physical systems that many Mesopotamian low sinuosity "rivers" are indistinguishable from canals (indeed the Sumerian language fails to make this distinction). Moreover, despite the extremely low gradient terrain, the distribution of irrigation water is made possible by directing water down levee slope canals that derive their water from the levee crest channel. Such levee slope canals, being steeper, are better for distributing irrigation waters than the gentle longitudinal gradients of the plains. Ironically, levee aggradation within this coevolutionary cultural landscape appears to have made irrigation much more sustainable in the long term.

Like their counterparts in central Asia, both the South Arabian and Mesopotamian landscapes reflect complex interactions between riverine, cultural, and aeolian processes. In southern Arabia, both lowland and highland soils have received long-term additions of aeolian silt, but in the immediate vicinity of eroded fields, sand dunes predominate as a result of the erosion of the silt beds. On the other hand in southern Iraq, aeolian dunes are composed of silt/clay aggregates (*parna*), as well as fragments of mollusc shells and small fragments of pottery and burned brick. The geoarchaeological cycle in these decidedly cultural landscapes is not simply one of progressive aggradation. Instead, aggradation appears

Hydraulic Engineering: Geoarchaeology, Fig. 7 Rectilinear erosion defining canals and field plots in Yemen. (Courtesy of Google Earth). The east–west extent of the fields is roughly 700 m (north to top), and each rectangular parcel measures c. 50 m east–west × 35–40 m north–south. *Dark masses* are outcrops of igneous rock

best developed where irrigation with turbid waters resulted in a steady input of sediment. However, where or whenever such input of water and sediment ceased, the landscape became desiccated resulting in a renewed cycle of aeolian degradation. Consequently, whereas parts of the landscape aggraded, other parts experienced aeolian degradation thereby resulting in a complex vertical or horizontal patterns of accumulation (Wilkinson 2003: 80–85). In addition, salts, ultimately derived from the irrigation waters, accumulate within the sediments and seriously depress crop yields especially in lower, less well-drained terrain.

Similar deep accumulations of irrigated soils occur in South America, Central Asia, and China. In Peru, the Palpa Valley in the hyperarid coastal desert received irrigation water from sediment-laden rivers over some 3,500 years (Hesse and Baade 2009). The 4 m accumulation of fine-grained irrigation deposits contain well-defined irragric anthrosols defined by the following characteristics: (1) absence of bedding or laminations; (2) common presence of artifacts or charcoal; (3) high loss on ignition, poor sorting, and high clay to silt ratios; and (4) presence of clods from agricultural turbation. These characteristics are similar to equivalent horizons in southern Mesopotamia, where irrigated soils not only blanket the entire terrain (Fig. 8) but are recognizable by their prismatic soil structure, gray-brown color, and inclusions such as broken shell fragments and artifacts.

Gorbunov's classic descriptions of irrigated soils of Central Asia demonstrate that natural soils were transformed by three main processes: (1) eluviation as a result of additions of water, (2) formation of a new "agro-irrigational" soil horizon by the intake of suspended particles and dissolved substances contained in the water, and (3) increased biological activity within the soil because of cultivated crops and farming practices (Gorbunov 1968: 35). These processes, operating over centuries or even millennia, resulted in the incremental accumulation of distinctive irrigation horizons which also included earthy materials from canal deposits, old mud brick materials, as well as potsherds, small fragments of burnt brick, charcoal, and bones. Such horizons have been reported from the ancient oases of Khwarizm, Bukhara, Samarkand, and Murgab (Gorbunov 1968: 39). Owing to the variety of natural environments encountered in central Asia, no single type of soil resulted from such anthropogenic processes; hence, they were classified into a number of types which include meadow oasis soils, takyr oasis soils, serozem oasis soils, and so on (Gorbunov 1968: 43).

The Geoarchaeology of Runoff Agriculture

Investigations of runoff agriculture have resulted in a number of classic hydrological and geoarchaeological studies (e.g., Bruins 1986). Runoff agriculture can also be argued to have developed as a result of "niche construction" because it builds upon an elemental model that occurs in nature (the source–sink model). This model perceives desert land surfaces as comprising a mosaic of patches, some of which shed water and others which receive the water that is shed (Wilkinson 2003: 154–155, with references). Water accumulated in the sinks promotes denser vegetation, increases litter, and raises organic matter, which, in turn, can reduce runoff. Ancient communities scaled this process up, so that the water shedding and receiving areas became larger.

Hydraulic Engineering: Geoarchaeology, Fig. 8 Section through a Mesopotamian levee showing levee deposits (*2*) overlain by a late (Sasanian–Islamic) irrigated soil (*1*). The pre-4000 BCE palaeosol (*3*) leads up to a water channel of similar date (*5*). (From Wilkinson 2003: Fig. 5.4b)

The end product of this source–sink model includes the water supply cisterns of Islamic Arabia as well as the runoff systems of the Negev and southern Arabia (Wilkinson 2003: 154–155). This process of scaling up from small-scale features with small runoff areas to much larger contributory basins results in a continuum of features ranging from rain-fed terraces to the largest-scale diversion dams with catchment to field ratios in excess of 1:100. Because runoff and run-on areas are functionally and intimately connected, they form examples of geoarchaeological anthrosols or anthropic sediments in which physical and cultural factors are again intertwined.

Agricultural Terraces

Agricultural terraces, which belong to the lower end of the runoff spectrum, can result from the accumulation of colluvial deposits on hillslopes as a result of localized runoff, although some are engineered, planned, and built up by soil introduced from elsewhere. However, they are generally a product of the efforts of thousands of households who constructed vast numbers of walls to accumulate and thicken the soil to grow crops, a system of intensification often known as *landesque* capital (Erickson 2006). Whereas most examples of terraced fields in the Middle East were constructed in relatively moist regions where rainfall exceeded 400 mm per annum, in South America they tend to be built in semiarid regions and therefore required irrigation to maintain crop growth (Denevan 2001: 173). As with irrigation sediments, such accumulations behind terrace walls provide a rich archive of sedimentary history and soil formation (Fish 1994: Fig. 3.1). The complexities of terrace classification and construction are beyond the scope of this entry, but overall, terraced fields provide thicker soil horizons capable of holding more moisture and providing greater rooting depth. Although they play a role in soil conservation, this is probably a secondary effect.

Illustrative of the role of terrace accumulations in soil improvement are the terraces of the Peruvian Andes. In the Colca Valley terrace soils differ significantly from their non-terraced counterparts (Denevan 2001: 192–193): A horizons are thicker and phosphorous, nitrogen, and organic carbon levels are higher, as are earthworm activity, friability, and water capacity. These differences result from centuries, or more than a millennium, of agrarian use which includes the application of fertilizers, manure, hearth ash, garbage, and crop residues (Denevan 2001: 193; Sandor and Eash 1995).

Terraced fields and associated soils represent a fragile resource, in part because they must be maintained by a large, industrious population. Any change to this demographic, or perhaps to the climate or cultivation techniques, can destabilize the system so that the accumulated soils become gullied, terrace walls eroded, and the landscape fabric weakened (Pietsch and Mabit 2012). One outcome of terrace degradation is that more sediment is delivered to valley floors and drainage channels thereby contributing to the development of valley fills (Butzer 1982).

The Geoarchaeology of Drained Landscapes

Hydraulic engineering is not only limited to water supply, it has also played a crucial role in the drainage of both coastal and interior wetlands, especially in NW Europe. Although the Fenlands of eastern England were probably not drained during the Roman period (Rippon 2000: 76), examples of Roman drainage and associated sediments come from the coastal lowlands along the Severn Estuary, UK. This top-down and piecemeal land management and drainage system, together with its geoarchaeological archive, shows wide-ranging evidence for sedimentary structures and soil drainage in the form of "ripening" (Allen and Fulford 1986).

Paddy Soils

Rather than being a specific soil type, the term "paddy" refers to the land use associated with the growing of wet rice. Nevertheless, the associated soils have a long history extending back to the Chinese Neolithic c. 6000 BP. For example, at Chuodon in the Yangtze river, valley fields were associated with paddy soils, ridged boundaries, and irrigation ditches. Phytolith and soils analyses demonstrate that the Neolithic paddy soils exhibited increased organic carbon, total N, P, and S, all of which were higher than peat or moss of the same age (Lu et al. 2006).

As with many Asian soils which experienced agricultural intensification, paddy soils and their staple crop of rice underpinned agricultural and population expansion, first with the development of gley soils on the lowlands and later on to sandy soils and Pleistocene terraces (Barnes 2010: 330–331). However, according to estimates of future sea level rise, the "rice basket" of the Japanese coastal plains is at risk of being diminished if not lost, thereby forcing agriculture on to higher slopes and terraces. Along with other examples of intensively cultivated hydraulic soils, paddy soils have played, and continue to play, a crucial role in provisioning and sustaining human communities.

International Perspectives

Despite the high-quality research conducted by Soviet-era and other soil scientists during the early twentieth century, the later part of the century witnessed only sporadic investigations of irrigated anthrosols. This was despite the fact that the term geoarchaeology was coined at this time. Nevertheless, a recent upsurge in research on anthrosols of various types promises to improve matters, because as the examples from Japan and China illustrate, a wide range of soils developed under intensive cultivation are under investigation. Unfortunately the irrigated soils of southern Arabia and Iraq together with associated terrace soils have benefitted from only sporadic geoarchaeological investigations. In contrast, equivalent features in Latin America have received significant and growing attention; therefore, just as the anthrosols of the Amazon basin have garnered justified interest, we should now expect to see increased research on irrigated and other anthropogenic soils.

Future Directions

The geoarchaeology of hydraulic structures and associated soils and sediments should be a major priority not only for their intrinsic interest but also because of the understanding they contribute to sustainable agriculture. Of course, limited access to soil resources in conflict-ridden countries such as Yemen and Iraq will probably continue to inhibit research. Moreover, assessment of the associated landscapes is inhibited because agricultural activities over the last 40–50 years (or more) have expunged many diagnostic features such as canals and scrambled the associated soils so that they are less recognizable than hitherto. Nevertheless, the existence of high-resolution satellite images of the CORONA program dating from the 1960s and 1970s provides a record of what has been lost. Consequently more use should be made of integrated programs of landscape assessment that combine satellite imagery with fieldwork down to the scale of soil micromorphology.

Dating techniques such as AMS radiocarbon dating and OSL should continue to be important, and the latter technique, still underused, promises to contribute increasingly to the dating of sedimentary sequences. As is evident from studies such as Hesse and Baade (2009) and Sandor and Eash (1995), "conventional" techniques of soil analysis continue to yield important results and demonstrate that irrigated and anthropogenic soils have played a key role in the rise and sustenance of early states.

Because the landscape archaeology of ancient water management has been rather neglected (but see the journals *Water History* and *Geoarchaeology*), the framework of hydraulic engineering and the geoarchaeological context has also been under-investigated. Nevertheless, the situation is changing rapidly, and this topic should be much more thoroughly understood and appreciated in future. Finally, it is crucial to appreciate that the soils described here result from the coevolution of humans with their "natural" environment. Consequently concepts such as human niche construction need to be harnessed in order to bring a theoretical perspective to what continues to be a very empirical field of investigation.

Hypothesis Testing in Archaeological Theory

Lisa J. Lucero
Department of Anthropology, University of Illinois Urbana-Champaign, Urbana, IL, USA

Introduction

In 1962 there was a "revolution" or paradigm shift in American archaeology, which became known as new or processual archaeology. At the forefront was Lewis Binford, closely followed by his colleagues and students, particularly Sally Binford, James N. Hill, William Longacre, Kent Flannery, Patty Jo Watson, Steven LeBlanc, Charles Redman, and others. Their works became classics, including James N. Hill's seminal article on Broken K Pueblo (1968). The five major tenets of this novel approach, especially in contrast to traditional or "old" archaeology, are the following: (1) the questions archaeologists ask – how and why in addition to what, when, and where, that is, the study of cultural process in addition to culture histories; (2) the theories used to explain past lifeways (vs. a list of traits that represent beliefs, ideas, and societal norms), especially cultural ecology and the assumption that culture is the extrasomatic means of adaptation; (3) use of the scientific method – that is, testing hypotheses with independent data; (4) the assumption that variation and change are perceived as representing adaptations to changing environmental conditions vs. the traditional view of innovation and diffusion; and (5) going beyond detailing stratigraphy, classifying artifacts, dating and emphasizing norms at the expense of explaining variability, and using regional survey, systematic excavations, sampling, statistics, etc. This entry focuses on the third tenet, the scientific method, specifically hypothesis testing, and by doing so highlights how it can be used apart from new or processual archaeology for its own sake since it can strengthen any approach or theoretical explorations of past societies.

Definition

Theory is a broad level of explanation (e.g., theories about evolution). Middle-range theory, another concept coined by Binford, is the step-by-step process and justifications of a research design that connect data and theory to avoid leaps of logic. Method is the strategy used to explicate and support a theory, and one such means is the hypothesis testing method composed of "if. . . then. . ." statements, arguments of relevance, and test implications. For example, if Structure X served as a kitchen, then we should find evidence for cooking, storage, and serving activities. The argument of relevance is that throughout the world, people cook, store, and serve food in kitchens. Test implications include finding an oven or hearth, wide-orifice jars or containers used for cooking (burned on bottom, carbonized remains inside vessels) and storage (no burning), nonporous narrow-orifice jars or pitchers used for storing and pouring liquids, possible ladles and other stirring and serving implements, and bowls, dishes, and plates for serving the prepared foods.

By following this step-by-step procedure, others can replicate methods and come to the same results; in this case, that Structure X did or did not serve as a kitchen. How archaeologists explain the place of Structure X in their interpretative framework varies depending on their interests, research problem, and/or theoretical leanings.

Archaeologists generate hypotheses or expectations often through using ethnographic analogy; for example, we use bowls to contain hot or cold liquid comestibles such as soup, ice cream, punch, cereal with milk, and so on. This deductive reasoning stands in contrast to inductive reasoning, whereby one collects data, somewhat indiscriminately, and generates conclusions (i.e., inductive inferences; Hempel 1966: 10–11) once data are classified. That said, inductive reasoning can make deductive reasoning easier since some conclusions in turn become hypotheses; after all, patterns often are revealed while one counts and classifies data. Deductive reasoning takes ideas to the next level by generating questions and

testable hypotheses that are tailored to support or disprove the patterns in the data or generated from external ideas via the ethnographic record, ethnoarchaeology, experimental archaeology, current practices, and even Eureka moments. Hypotheses are set up in such a way to be supported (rather than proven) or disproven; in other words, they are falsifiable. In addition, hypotheses can always be supplanted by better ones as methods and techniques improve and ideas advance. It is a way to verify, or not, ideas that are generated to support or explain broader research questions.

A further way to strengthen theories or arguments is through generating and testing multiple or alternative hypotheses, which serves two major purposes: (1) shows peers that one is not invested solely in one idea; and (2) the hypotheses may turn out to explain different aspects of the research question or problem. Then of course there is the null hypothesis, which is a hypothesis completely opposite of what is actually expected, which only supports the main hypothesis if it is disproven. Alternative hypotheses also prevent biases and the collection of data that promotes one idea over another, not to mention promoting thoroughness (Chamberlin 1965[1890]). For example, using the kitchen hypothesis above, a null hypothesis would go something like this: if Structure X did not serve as a kitchen, then we would expect to find non-kitchen items (ritual objects, sleeping areas, public iconography, etc.). Alternative hypotheses could be, for example, the following: (1) if Structure X served as a storage room, then we would expect to find storage containers and no windows; (2) if Structure X served as a religious building, then we would expect to find ceremonial and religious paraphernalia (e.g., altar, incense burners), iconography, and seating; and (3) if Structure X served as a residence, then we would expect to find diverse ceramic/container types, sleeping, living, and cooking areas/furniture and utensils, etc.

No matter which hypothesis is supported (or refuted), one still has to explain it since data reflect human behavior and archaeologists are asking basically humanistic questions (Praetzellis 2000). For example, in a study on assessing ceramic variability in ancient Maya hinterland households to assess wealth and status (Lucero 2001), one of the original hypotheses was that elite residences should have larger and a greater number of vessels reflecting larger households consisting of family and nonfamily members. However, some of the smaller, commoner, houses had more vessels (though not necessarily larger vessels). This unexpected finding was explained by the fact that some commoner residences house more people to pool their labor and resources (this inference would have served as an excellent alternative hypothesis as well).

Using the hypothesis testing method prevents the collection of data just for the sake of collecting data; it requires scholars to start with a problem and devise hypotheses to address the problem, which in turn structures the type of relevant data to collect and process.

Historical Background

Walter W. Taylor in his 1948 *A Study of Archaeology* critiqued traditional archaeology (1983 [1948]), and rather than leave it at that, he suggested that archaeologists should take a "conjunctive approach" that combined the best of archaeology and anthropology. While he focused on American archaeology, the implications were international. He called for a well-rounded interdisciplinary approach to reveal past lifeways, including focusing on settlement patterns; subsistence; social, religious, and political organization; and diet through rigorous excavation and recording techniques. It was only through taking such an approach that archaeologists could present a fuller picture of past societies. Taylor's call to arms was not taken up until the 1960s with the advent of new archaeology advocated by Lewis Binford and his intellectual entourage.

In 1962, Lewis Binford published his now classic article, "Archaeology as Anthropology," in which he details the goals of what soon would be referred to as new archaeology. Archaeology's goal should not be to compile data just for the sake of compiling data without a framework to guide collecting strategies. Past societies are not

comprised of artifact lists; rather, artifacts are the remnants of once-living people who no longer have a voice. Artifacts are not history; they reflect the behaviors of the people who made them, which in turn reflects how people/society adapted to their particular environment, practiced their faith, and organized their economy, social interactions, and political systems – in other words, how they lived. It is up to the archaeologist to come up with the means to not only give voice to the past, but to do it in such a manner where peers can both understand and replicate results. Hypothesis testing accomplishes this goal.

Key Issues, Current Debates, and International Perspectives

There was a backlash to processual archaeology beginning in the 1980s, and critics absolved themselves of anything having to do with new archaeology (Earle and Preucel 1987). Some criticisms were valid, especially those regarding new archaeology's theoretical constructs (e.g., environment is the *key* factor) and some of the techniques used (e.g., statistics alone, models from the hard or physical sciences) (e.g., Hodder 1982, 1985, 1986). In doing so, however, some archaeologists have left themselves open to claims of fictionalizing the past, which is not the intent of sound scholarship. Using the hypothesis testing method allays this problem because it is about *replicable research*; it is about ideas that one attempts to confirm, but cannot prove. Other scholars should be able to use the same methods and come up with the same results; of course how people interpret those results is another matter entirely and depends on their theoretical interests. When a backlash occurred, many archaeologists were too ready to throw the baby out with the bathwater – specifically, the use of the hypothesis testing method because they did not evaluate it independent from processual archaeology rather than evaluating it as a method on its own merit. However, sound scholarship requires a degree of accounting to colleagues and peers, and hypothesis testing is critical for this end.

This point is illustrated using two recent papers: one on Classic Maya commoner cosmology and the other on ancient Maya witches.

A recent article (Lucero 2010) on Classic Maya commoners, summarized here, focuses on rituals that took place in the home to reveal the materiality of cosmology in the built environment. In the ethnographic present, Maya domestic ceremonies revolve around life, death, and renewal, which are reflected in the importance of dedication, ancestor veneration, and termination rites. Dedication ceremonies animate new houses and include the caching of objects under house floors. Ancestor veneration rites honor and thank ancestors and involve interring deceased family members with or without grave goods in house floors. Some Maya refer to children as *kexol*, or "replacements," signifying the connection between the living and the dead (Schele and Miller 1986: 266). Grave goods tell us much about the deceased family member; for example, among the Zinacantecos of Chiapas, grave goods "are said to possess the soul of their owner" (Vogt 1998: 28). Termination ceremonies deactivate or de-animate houses, thus releasing their soul before renewal, and include breaking objects, partially destroying houses, and burning incense. Renewal is necessary after the death of a family member when life must begin anew. The Maya conduct these ceremonies in memory of ancestors that all could witness, family and non-family alike.

Hypothesis: If pre-Columbian Maya practiced dedication, ancestor veneration, and termination rites in the home, then we should find caches, burials, and broken artifacts in the home. Argument of relevance: since these rites come from a long-standing tradition that is still practiced at present, the Maya likely practiced them in the past. Test implications (Table 1): caches should be found beneath floors consisting of burned or unburned whole objects such as jade items, obsidian, grounding implements, eccentrics, and ceramic vessels; burials, typically with grave goods, should be found under house floors, and deposits should be found on floor surfaces consisting of broken and burned items, such as ceramic vessels.

Hypothesis Testing in Archaeological Theory, Table 1 Revealing commoner ritual in the home

Hypothesized ritual	Test implications
Dedication	Whole objects sealed under floors
Ancestor veneration	Burials in floors with or without grave goods
Termination	Broken and burned items on floor surface

These test implications are evaluated at the ancient Maya minor river center of Saturday Creek, Belize. The Maya lived in this community from at least 900 BCE to 1500 CE in dispersed farmsteads consisting of solitary mounds and mound groups or *plazuelas* (Lucero 2006). A ball court, temples up to c. 10 m tall, and elite compounds comprise the site core. Archaeologists excavated two solitary mounds or commoner residences (SC-18 and SC-85), an eastern structure of an elite compound (SC-78), and a temple ball court (SC-3). This focus here is on the two smaller residences, which the Maya occupied from c. 400 to 1150 CE.

Under the floors in fill, archaeologists recovered obsidian blades, mano and metate fragments, polished bone and stone, bone needles, modified and unmodified marine shell, chert cores, spindle whorls, a celt, a bark beater, faunal remains, figurine fragments, ceramic discs, and a few small jade and hematite inlay or mosaic pieces. Twelve burials were recovered from the commoner houses, most with grave goods. Several deposits of smashed and burned vessels were found on floor surfaces. Evidence supports the hypothesis that the pre-Columbian Maya practiced dedication, ancestor veneration, and termination rites in the home.

Any archaeologist would recover the same materials and, by using the hypothesis testing method, come up with the same results – that the Maya cached items in floors and sealed them, interred the dead into house floors, and burned and broke items before putting down a new floor with its own caches. History and ethnography reveal that these ritual behaviors reflect dedication, ancestor veneration, and termination practices at Saturday Creek throughout the entire occupancy of the houses, over 600 years – from c. 400 to 1150 CE. Interpreting these results, however, can vary depending on the questions asked. The article's focus on materiality, memory, and cosmology shaped interpretations. Briefly, the Maya performed traditional rites for over a millennium, and they conducted them for family and members of the community to acknowledge a family's loss – and new beginning. People interred the dead to create ancestors who remained involved in the lives of the living. Domestic ceremonial practices, by their materiality, solidify inhabitants' ties to family and community. Building and destroying houses was closely tied to the life history of ancestors. Memory and place were created in the cycle of dedication, ancestor veneration, and termination rites. In fact, Maya occupied most houses continuously for centuries, suggesting that they became "a key element in the maintenance of cultural memory" (Chapman 2000: 4).

Another example of the hypothesis testing method concerns exploring ancient Maya witchcraft persecution (Lucero and Gibbs 2007), summarized here. Throughout the world, witchcraft persecution occurs in times of stress, including untimely deaths, drought, floods, famine, or disease. Witches are people who are blamed and punished, often violently, for perceived or real problems by community census.

There are various forms of witchcraft in the Maya ethnographic present, as was the case during the Colonial period. For example, among the Zinacantecos of highland Chiapas, Mexico, when people come to the Ceremonial center from different villages for major rituals, "There is always the danger... that harmful witchcraft rituals may be carried out by envious members of other lineages" (Vogt 2004: 44). Witchcraft accusations also take place within communities, and "If someone has sinned and is condemned by his kinsmen and neighbors as a witch..., public denunciation and ritual neglect may characterize the funeral, and the soul is banished to *K'atinbak*" – a "place warmed by bones" and "a deep hole inside the earth" (Vogt 1998: 29). In Chiapas, animal spirits or companions are associated with sorcery, and combat between them brings

misfortune and disease. In the Yucatán, it is believed that people can turn themselves into animals at night for evil purposes – that is, witchcraft.

People respond against witchcraft with violence. Spanish chroniclers noted that elderly Maya women were selected by villagers as scapegoats in times of trouble and stoned to death. For the Tzeltal Maya of Amatenango, Chiapas, of the 36 homicides recorded for 1 year in the late 1960s, over half had been accused as witches, and most were men ($n = 19$ or 53%). And of the nine *curanderos* (traditional healers) on the list, all had been accused of practicing witchcraft. In an Associated Press release dated September 16, 2002, a recent attack is detailed: "Unidentified gunmen burst into the home of an alleged practitioner of witchcraft in… Chiapas and shot to death four adults and wounded five other people, including two children." The same release also stated that there have been several "witches" killed in the past decade in Chiapas, a practice that also occurs throughout the rest of Mexico and Central America.

Evidence from ethnohistoric and ethnographic records also suggests a long history of the belief in witchcraft's association with openings in the earth. Caves, for example, are portals to the underworld or Xibalba and thus are sacred but dangerous places. Bishop de Landa in colonial Yucatán noted that people, particularly young boys, were sacrificed when the rainy season was overdue or during a famine; victims were thrown into *cenotes*, natural sinkholes – another portal to the underworld. In general, infants, children, and young adults may have been sacrificed as innocents, whereas some adults may have been killed/sacrificed as evildoers – that is, witches. In Zinacantan, people associate caves with witches and believe that witchcraft ceremonies take place within them. "Soul loss can… occur when an evil person performs a witchcraft ritual in a cave to "sell" the inner soul to the Earth Lord, who then uses the person as a servant" (Vogt 2004: 30). In the 1990s at the height of the paramilitary killings in Zapatista Chiapas by *cortacabezas* or headcutters, two male teenagers from San Pedro Chenalhó who had bragged about being Zapatista supporters were stoned to death for bringing disharmony to the community. The Maya unceremoniously dumped their bodies in a crevice, another kind of opening in the earth. In another case that took place in 1648 in Guatemala, people witnessed a battle between animal or spirit companions (a puma and jaguar) of two Pokomchi Maya. One died of his wounds, while the other eventually was hanged for the "murder," and his neighbors placed his body in a ditch in a shallow grave rather than in a church-sanctioned cemetery. These and other cases illustrate the belief in witchcraft and its association with violent death, non-funerary treatment, and openings in the earth, especially caves.

Lucero and Gibbs propose that witch killings have a long, pre-Columbian history. Witch killings actually might have been a community response in times of extreme stress where people felt they had no other choice but to sacrifice someone, usually a member of the their own community. It was not enough to kill witches; as dangerously animated items, they were deposited in dangerous places, safely away from the living – that is, in caves.

The challenge, however, is to distinguish ancestors and sacrificial victims from witches. This feat is particularly challenging since caves likely entombed ancestors, sacrificial victims, *and* witches. In fact, witches and sacrificial victims in one sense can be perceived as one and the same. People can be sacrificed for the same reasons witches are killed – to restore order. Sacrificial victims, however, are accorded respect after death, so they can enjoy the afterlife in paradise. Witches, in contrast, are malevolent and thus are treated differently after death.

Hypothesis: If ancient witches existed, then we should expect to find evidence of this in *peri-* and *postmortem* treatment of certain people. Specifically for the Maya case, if human remains in caves show evidence for violence and non-funerary treatment, then they might represent killed witches. Argument of relevance: since witches are typically violently killed and not buried with non-witches worldwide and in the Maya area at present, we should expect to find the same to have been the case in the past. Test implications (Table 2): distinguishing witches from sacrificial

Hypothesis Testing in Archaeological Theory, Table 2 Defining the dead

Hypothesized classification	Test implications
Ancestor	Buried, positioned, grave goods, no evidence of trauma
Sacrifice	Buried, positioned, grave goods or not, evidence of trauma
Witch	Not buried, not positioned, no grave goods, evidence of trauma

victims and ancestors in caves is possible through an analysis of the context of remains (buried or not), disposition of bodies (e.g., evidence of binding, proper placement), evidence for trauma, and the presence or absence of grave goods. Ancestors were buried in orchestrated positions with grave goods and without trauma, sacrificial victims were buried with or without grave goods with trauma, and witches were neither buried nor positioned, did not have grave goods, and show evidence for trauma.

Briefly summarized here is the context of skeletal data from two caves that represent the majority of lowland Maya cave deposits – Actun Tunichil Muknal and Actun Uayazba Kab in central Belize. They were predominantly used during the Classic period, especially in the Late Classic or 700–900 CE. Major differences between the two caves are the context of remains – surface or subsurface and presence or absence of trauma and grave goods. Most individuals in Actun Uayazba Kab, a shallow cave/rockshelter, were carefully placed and *buried* beneath a plaster floor, along with offerings. In contrast, Actun Tunichil Muknal goes deeper – 5 km – into the mountain, that is, closer to the sacred, and dangerous. Half of the 14 individuals, all found unburied, show evidence of cranial trauma. After they were killed, the Maya left the remains on the surface – without offerings. Evidence supports the hypothesis that ancient Maya witches existed.

Actun Uayazba Kab demonstrates more evidence for funerary rites and the creation of ancestors, who were kept relatively close to the living in a "lineage mountain" nearby a small center. In Actun Tunichil Muknal, the dead were not accorded traditional burial rites. By killing a witch, the Maya deactivated their evil power. The living left dead witches exposed to the elements or the perilous underworld without any protection. By offering such individuals, the living condemned their spirits to the malevolent gods of the underworld in hopes of restoring order.

The purpose of this exercise has been to demonstrate the importance of using the hypothesis testing method in archaeology. Methods are replicable, though interpretations can and do vary. Rigorous methodology is a must in a field where we give voice to the people of the past. Insulting their memory with insupportable claims is poor and irresponsible scholarship. Embracing new ideas, theories, and thinking outside the box are vital to give voice to the past. Giving power to that voice requires us to work largely inside the box, methodologically anyway.

Future Directions

It is critical that archaeologists, and all social scientists and humanists, teach their students the importance of using replicable methods; this will allow their peers to follow, step by step, how one obtained their results. This is what scholarship is all about; revealing to our best abilities the voices that have been quiet too long. This is a serious endeavor and one that requires rigorous methods. In fact, many archaeologists use hypothesis testing, whether or not they use the "terminology" or are even aware of it.

No matter one's theoretical interests (e.g., see Preucel and Mrozowski 2010), the undeniable fact (not a theory) is that archaeology deals with the material world into which archaeologists are attempting to breathe history and life. Archaeology is always borrowing theories and ideas from other disciplines, which is a critical component of fulfilling the goal of bringing the past back to life. But how one accomplishes this can be contentious unless peers are able to replicate results. The hypothesis testing method is such a method and its use allays this problem. Facts can be filtered through replicable methods to obtain results that will only enhance interpretations.

Iberia: Medieval Archaeology

Juan Antonio Quirós-Castillo
University of the Basque Country, Vitoria-Gasteiz, Spain

Introduction

Medieval archaeology in Iberia is a relatively young discipline that aims to study the societies of the Hispanic landscape during the millennium spanning from the fifth to the fifteenth centuries (the traditional key dates remain the fall of the western Roman Empire in 476, and the conquest of the Nasrid dynasty of Granada and the discovery of the Americas, both of which occurred in 1492) (Fig. 1). From its very beginnings (in Iberia), archaeological study has been oriented toward the study of the material manifestations of Islamic society (*andalusí* archaeology) and Christian society (early medieval archaeology and feudal archaeology). The three characteristics that define its practice are: its underdeveloped academic profile; the role that rescue archaeology has acquired in recent years; and a notable atheoretical quality which has manifested itself via a striking dependence on the paradigms and approaches favored by medievalists working with textual sources, as well as a lack of epistemological and methodological reflection.

Definition

Medieval archaeology in Iberia encompasses many "archaeologies" with different chronological and thematic concerns, all of which are the result of diverse conceptual and historiographical approaches and have had, until recently, different academic trajectories.

After the collapse of the Roman Empire, various Germanic groups occupied *Hispania* in the fifth century, although only the Sueves (in the northwest of the peninsula) and the Visigoths managed to establish stable kingdoms. Archaeological analysis of these early medieval centuries has given rise to a specific "archaeology of the Visigoths" which is profoundly marked by cultural historicism. Alternatively, the study of the origins of Christianity and its early monuments has produced a paleochristian archaeology characterized by art-historical concerns. All of these trends have been supplanted in the last three decades by "early medieval" archaeology, which has been oriented toward the social aspects of landscape study, and based upon data provided by numerous excavations in cities, monumental spaces, and rural areas.

One of the principal particularities of the Iberian peninsula during the Middle Ages is the coexistence, over many centuries, of feudal political formations alongside Islamic state-based polities, after the conquest of the Visigothic kingdom

in 711. The historical development of the territory dominated by the Islamic states, known as al-Andalus (in classical Arabic دلس), took the course it did in part as a result of the growing pressure exercised by feudal powers to the north (a process traditionally known as *reconquista*), and in part because of internal historical dynamics, which ultimately led, at the very end of the Middle Ages, to the defeat of the Nasrid Kingdom of Granada. *Andalusi* archaeology has been concerned primarily with the study and characterization of the state and society of al-Andalus.

Furthermore, the study of the northern kingdoms and their territorial expansion has been undertaken within the methodological context of feudal archaeology, which has explored the similarities and contrasts between medieval societies, focusing particularly on themes such as the formation of villages, the emergence of seigneurial powers, the process of *incastellamento*, the role of castles, and the study of medieval urbanism.

Such a division, in truth, is arbitrary and inexact, given that it marginalizes minority groups (Hebrews, Mozarabs ["Arabised" Christians] and *Mudéjares* [Muslims in Christian territory]) and, above all, fails to reflect the complex and changing reality of territorial control. On the other hand, although in academic circles, there has existed a profound disjunction between feudal and *andalusí* history and archaeology, a significant number of researchers have made use of this great diversity, employing comparative methods in order to overcome a certain idealized historicist backdrop and develop more complex theoretical insights. The influence of Italian medieval archaeology has played a key role in providing medieval archaeology in Iberia with a sound theoretical and methodological background.

The limited presence of medieval archaeology in the university sector (taught in only a dozen institutions in Spain and Portugal) has meant that museum-directed work and rescue archaeology have been fundamental in the study of medieval urban and rural contexts. In 1985, the Law of Spanish Historical Heritage and the Law of Portuguese Cultural Heritage were promulgated,

which have provided a solid platform for the development of rescue archaeology. The frenetic pace of urban building activity and the enormous number of public building projects undertaken in Iberia in the last 20 years have brought in their wake the excavation of a high number of medieval settlements, and even led to the discovery of a new type of settlement, known as the peasant farmstead and the peasant village. And although the majority of these findings remain unpublished, the qualitative leap to which the last few years have borne witness is striking.

On the other hand, the quantity of well-preserved medieval architectural monuments and the high number of restorations undertaken on these former has meant that in Iberia and Italy, the archaeological study of architecture has gained importance in recent years. The so-called Archaeology of Architecture, which supports its own specialist publication, has been applied both in the realization of studies that precede the restoration of buildings, and in the documentation and intensive study of groups of buildings, such as the early medieval churches of Spain.

Historical Background

The origins of medieval archaeology in Iberia can be found in the second half of the nineteenth century and the first decades of the twentieth, when the first antiquarian studies (largely numismatical and epigraphical) were undertaken, as were the first studies of monumental architecture, occasionally as part and parcel of restoration programs. These were years in which a certain arabism developed, closely linked to a romantic fascination with an exotic orientalism, and in which archaeological practice was closely identified with the history of art, and – more precisely – with the history of architecture. At the end of the nineteenth century and the beginning of the twentieth, the first excavations were carried out in places such as Medinat al-Zahra, Bobastro, or the Alhambra in the south, as well as in castles, monasteries, and necropolises in the northern areas of the peninsula (e.g., Mendikute, Aitzorrotz, Pamplona, Santa María de Ripoll), and from 1912, courses in Arabic archaeology were offered in the Central University of Madrid. However, the consolidation of History of Art as a discipline in its own right, and a burgeoning change in theoretical approaches, meant that by 1920, this first phase of medieval archaeology in Iberia was losing momentum, coinciding, in this regard, almost exactly with a similar process seen in Italy.

During the dictatorships of Salazar and Franco, medieval archaeology was strictly limited to that which focused on searching for signs of Visigothic presence in Spanish territory, and this outlook would dominate medieval studies until the 1970s and 1980s, while in Portugal, a great number of medieval monuments were restored in order to exalt the glory of the "national" past. Furthermore, during this period, architects like L. Torres Balbás or F. Hernández undertook studies of monumental *andalusí* complexes, such as the Alhambra or Madinat al-Zahra. It was with the arrival of democracy, both in Spain and Portugal, that the foundations of modern medieval archaeological study were laid. Among the reasons which help to explain this change, one can point to a process of renovation with regard to theoretical and epistemological approaches to medieval Hispanic societies, a growing sensitivity toward the post-classical heritage – which was especially affected by restoration work and urban archaeology – and which constituted the precedent for the legislation of the 1980s, and the emergence of a new generation of researchers who began to build their careers in the margins of the ever-dominant classical and prehistoric archaeology.

In Spain, the first meeting of medieval archaeologists took place in 1980 and this provided a platform for the foundation of the Spanish Association of Medieval Archaeology in the following year. The Association played a major role in the early years, given that it also oversaw the creation of the journal (*Boletín de Arqueología Medieval*, 1986) and the organization of national congresses in Medieval Archaeology held in Huesca (1985), Madrid (1987), Oviedo (1999), Alicante (1993), and Valladolid (1999). Nonetheless, the institutionalization of archaeology in the universities and the emergence of rescue archaeology in the

1990s posed a challenge to which the Association has been unable to adapt, and for this reason, it has now lost its function and purpose.

Throughout the early stages of medieval archaeology in Portugal, the achievements of some university lecturers (C. A. Ferreira de Almeida, H. Catarina o R. Varela) have been notable, as have initiatives from beyond the academic sphere, among which that led by C. Torres at the Mértola's Archaeological Site stands out (alongside its house journal *Arqueología Medieval*, published since 1992). In the 1990s, a whole series of congresses were held which allowed for the systematization of the archaeological study of the ceramic record (Tondela, 1992–2000), castles (Palmela, 2000), and Christian monuments (Lisbon, 1992), each of which was broached from a wide geographical and theoretical framework; the first studies of a certain stature were also produced in this period.

During the 1980s, the majority of studies were oriented toward the systematization of the ceramic record, the analysis of settlement patterns, and the creation of inventories within a wider framework of regional archaeological studies. Since the 1990s, substantial archaeological projects have begun to take place, as have intensive regional studies across the peninsula, which has allowed for the creation of a significant research agenda.

The publication in 1988 of the M. Barceló book under the provocative title of *Arqueología Medieval. En las afueras del medievalismo* marked a true turning point. This text, defined by the author as a "methodological reflection," aims to draw attention to the most theoretical and conceptual aspects affecting the growth of medieval archaeology, and affords methodological aspects of the discipline a secondary role. A strong denunciation is made of the way in which archaeology finds itself outside of mainstream "medievalism" (understood as the academic approach to medieval history), and relegated to the status of an auxiliary discipline, illustrative of thematic concerns raised in earlier times. On the other hand, the book reflects the notable influence that historical materialism has enjoyed in studies of medieval societies since the 1980s, and as such proposes an investigative program of conceptual complexity in which the archaeology of peasant society is proposed as one of the major research concerns. This was a time in which the practice of rescue archaeology (characterized by a notable empiricism, itself a reflection of the weak influence of academic training among archaeologists) truly took off.

During the 1990s, *andalusí* archaeology has experienced significant development in both Spain and Portugal, as can be evidenced by the convocation of a high number of meetings and the publication of the journal *Arqueología y Territorio Medieval* (Jaén 1993), with the result that works there from have begun to form part of a wider European debate on medieval societies.

Similarly, the profound innovation signaled by the application of the archaeology of architecture to churches such as San Juan de Baños, San Pedro de la Nave o São Gião de Nazaré, and the practice of urban archaeology in centers, such as Valencia, Tarragona, Recópolis, Mérida, Mertola o Braga, has had a profound impact upon the archaeological study of early medieval societies. In the last 15 years, the contribution of rescue archaeology has been equally decisive when it comes to the study of early medieval rural society.

Conversely, the emergence of the archaeological study of feudal societies has been slower, taking place over the last decade. The majority of these analyses have focused on the process of the formation of lordships, paying little attention to the later Middle Ages.

Key Issues

The Archaeological Study of *andalusí* Society: The Process of Islamisation

One of the principal contributions of Iberian medieval archaeology has been the study of the formation and articulation of *andalusí* state and society. Spanish historiography before the 1980s had questioned and underestimated the Islamic character of *andalusí* societies and a few scholars even went as far as denying that the Islamic conquest ever took place. The difficulties supposed by Arabic source material for most

"medievalists," together with the pervasive strength of nationalist conceptual frameworks, help to explain these limitations.

There are two major explanatory factors behind the subsequent renovation: On the one hand, we have the anthropological studies of P. Guichard, undertaken in the 1970s, which underlined the qualitative differences between Arabic and Berber tribal societies in al-Andalus, and Christian societies; second, the analyses of M. Acién delineated a process of transition during the Emiral period (755–929) which could be explained by way of reference to competition between various modes of production (tribal, feudal, and Islamic), and which was resolved by the imposition of a strong and hegemonic state in the tenth century (the Umayyad Caliphate, 929–1031) that prevented the consolidation of regional lordship in al-Andalus.

Building upon these suppositions, regional landscape studies have been undertaken in Granada, the Guadalquivir valley, and the Levante region, which have analyzed the transformation of rural settlements, cities, and the twin phenomena of production and circulation (of goods and peoples) throughout the period of Islamicisation. And although consensus has yet to be reached with regard to the weight of continuations (e.g., the persistence of feudal trends throughout the Emirate, the roots of which can be traced to the late Visigothic landowning class), it has been established that the Islamic invasion brought with it a profound social, economic, and political break. S. Gutiérrez has shown how numerous urban centers occupied in the Visigothic period were radically transformed during the Emirate (El Tolmo de Minateda (Fig. 2) and Recopolis are two such examples), only to be abandoned in the tenth century when other urban centers emerged to support the fiscal structures of the Caliphate (such as Murcia, Badajoz, and Almería). Other cities survived, like Mérida, Valencia, or Córdoba, but were notably transformed in architectural and urbanistic terms as complex multilevel dwellings ordered around a central patio were built, as can be seen in the Saqunda neighborhood of Córdoba. This urban network was articulated by a strong state-directed sociopolitical system that was most unlike that which we call the "feudal system." Rural settlements were also profoundly modified, thanks to various processes including the occupation of hill-top sites by peasant communities.

A second key factor in the archaeological study of *andalusí* society has taken the form of the analysis of rural landscapes, with the aim of shedding light on the fiscal system upon which the Caliphate and, later, the *taifa* kingdoms were built; thus, the material bases of *andalusí* society

Iberia: Medieval Archaeology, Fig. 2 The city of El Tolmo de Minateda (Albacete, Spain), according to Sonia Gutiérrez Lloret

Iberia: Medieval Archaeology, Fig. 3 El Cerro de Peñaflor (Jaén, Spain)

might be better understood. Insofar as the study of rural spaces is concerned, great attention has been afforded, in methodological terms, to extensive place-name analysis and intensive excavation; in practice, both habitational spaces and irrigated farm systems have been studied.

Since the 1980s, preeminence has been given in the eastern peninsula to the dual phenomena of *huṣûn* (fortifications) and *qurà* (*alquerías* or concentrated residential areas), which have been considered key elements in the organization of the rural population. *Huṣûn* did not enjoy lordly associations, but were rather the fortifications of peasant communities or central points within a network of state-organized defensive structures. We are faced, therefore, with a society without lords. *Alquerías*, still poorly understood, were perhaps an expression of unequal peasant communities which were nonetheless characterized by strong internal cohesion, as we have seen in Los Guájares (Granada) or at the Cerro de Peñaflor (Jaén) (Fig. 3).

Furthermore, the study of irrigated land and the social practices which developed around the process of managing the water supply has been another fundamental theme of *andalusí* archaeology. M. Barceló has argued that horticultural products were impossible to store in large quantities and thus commandeer as rent, instead being consumed by peasant cultivators, and that this prevented the taking of rent by lords.

The Formation of Villages and Medieval Farmland

Until relatively recently, peasant areas of habitation and production in medieval Iberia were practically invisible. Only a few settlements characterized by dwellings with stone plinths or foundations, or irrigated cultivable plots, together made up the limited evidential base with which attempts to understand the medieval peasantry were made. On the other hand, Iberian medievalism has assumed – following the paradigm of R. Fossier – that early medieval rural society was disperse and quasi-nomadic, and that, accordingly, it was only with the implantation of feudalism in the eleventh century that sedentary social structures came about, as the peasant landscape was reordered under seigneurial lordship.

Nonetheless, the boom in rescue archaeology that has taken place since the mid-1990s, especially in the outskirts of large cities like Madrid and Barcelona (Fig. 4), allied to the carrying out of large-scale excavations, has obliged us to acknowledge the existence of significant village settlements, visible by way of structures

Iberia: Medieval Archaeology, Fig. 4 Village of Gózquez (Madrid, Spain)

Iberia: Medieval Archaeology, Fig. 5 Tenth-century agrarian spaces of Zaballa (Álava, Spain)

excavated in the substrate (silos, sunken featured buildings, wells, enclosed areas) and constructions with stone foundations which represent the dwellings of peasant communities. Similarly, it has been possible to recognize spaces which can be characterized as "intermediate areas," lacking in archaeological material, which have been identified as farmland. In places like Galicia, Asturias, or the Basque country, it has been possible, moreover, to identify terraced areas and farmland from the medieval period, thanks to extensive excavation and the analysis of the material from these agrarian sites (Fig. 5).

The formation of villages in the Iberian peninsula took place in the early Middle Ages, although there are important regional differences to bear in mind. The creation of village networks was the result of the emergence of a new post-imperial political order that is visible in parts of the Meseta (where Visigothic power structures were at their strongest) or in parts of Catalonia (around cities like Barcelona). We lack, on the other hand, networks of stable villages in other parts of Iberia where the influence of local and central powers is clearly marked. It was from the eighth century, in wide sectors of the northern peninsula, that village structures underwent consolidation, in accordance with the formation of emergent proto-statist realities. In other parts of Iberia, like the Upper Mondego in Portugal, the formation of such villages has only been verified from the tenth century (Fig. 6).

By exploiting various mechanisms and processes, sociopolitical elites dominated these villages, either though the collection of rent, the domination of community resources, or, lastly, dominance over people. A correspondence between the distribution of village networks and centers of power has also been noted.

The Archaeology of Feudalism

Once the lack of correspondence between the process of village formation and the affirmation of territorial lordships had been recognized, an archaeology of feudalism developed with the objective of discovering, via the archaeological record, the social mechanism by which new forms of lordly power was established in the post-Carolingian period. The main sites in which this archaeological practice has been developed have been centers of power, in particular castles or churches, although in the past few years, it has been possible to analyze the transformations that took place in peasant villages, which latter present the most fruitful landscape for the analysis of the social action of elites.

In several areas of the north of the peninsula, it has been possible to observe the formation, from the eighth and ninth centuries, of centers of local power articulated around castles (such is the case

of Peñaferruz in Asturias) or private churches whose owners have important resources (such as San Román de Tobillas in Álava). The capabilities of these local powers differ from territory to territory, in such a way that they seem to be much stronger in Asturias or Galicia when compared to the Castilian, Aragonese, or Catalan areas. From the tenth century, it is possible to trace a certain process of the growing strength of local aristocracies able to control entire peasant communities and to alter the landscape. In areas such as Álava, it has been possible to see how, at this time, private churches, such as that at Zaballa, were built in the heart of peasant villages and took on roles as centers for the collection of rents, thereby altering the built environment of the village. The castle of Treviño was also built in this century, bringing together a peasant community within a walled area dominated by a lordly residence where rents were collected, following a classical pattern of Mediterranean *incastellamento*. Likewise, sufficient indications exist to speak of *incastellamento* or even of forms of concentration of peasant settlement around churches and their sacred spaces, in a framework of *ensangrerament* (Fig. 7).

Iberia: Medieval Archaeology, Fig. 6 San Gens (Upper Mondego, Portugal)

Iberia: Medieval Archaeology, Fig. 7 Castle of Treviño (Burgos, Spain)

Another line of research that has acquired notable importance has been the analysis of the process of transformation of *andalusí* landscapes after the feudal conquest. In particular, very detailed studies have been carried out on the modifications of the urban fabric in centers such as Murcia via the analysis of the disarticulation of Islamic dwellings, the creation of great avenues and communal spaces, the establishment of ecclesiastical centers or the organization of urban spaces. Additionally, the processes by which hydraulic systems were adapted to new social and productive logics by means of the introduction of hydraulic mills and the dismantling of irrigated lands in the east of the peninsula have also been studied.

Future Directions

Perhaps the main challenge presented by Iberian archaeology in general, and medieval Iberian archaeology in particular, is that of confronting the study and the publication of the many archaeological contexts that have been analyzed via the prism of rescue archaeology in the last 15 years. In this period, thousands of archaeological interventions have taken place every year in medieval contexts, although we lack precise details regarding their number. The logic of the market has meant that priority has been given to interventions that have concentrated on the documentation of sites prior to their destruction, allowing only on very few occasions the undertaking of projects that maximize the value of the potential information that might be drawn from such sites. Now that the financial crisis has practically put an end to the progress of rescue archaeology in the last 15 years, the time has come to produce publications about the numerous interventions that have been carried out. We lack monographs and a critical mass of studies proportional to the work done during recent years and, thus, this is one of the main priorities for the next few years in many parts of Iberia. Moreover, this initiative should bring about the publication of a great number of studies.

The second course of action that must be promoted in the future is that of Science Archaeology. By way of example, although there have been some exceptions, there have not been many studies undertaken in recent years from the perspective of environmental archaeology. This is one of the fields in which the distance between the practice of historical archaeology in the north and south of Europe seems most evident. The lack of sophisticated programs of sampling and of a dense network of geoarchaeologist and bioarchaeologists working in medieval archaeological contexts explain these shortfalls. The scarcity of studies in fields, such as archaeobotany, archaeofauna, or physical anthropology, also explains the reasons why we currently lack monographs and territorial syntheses of substance. This tendency is reversing, thanks, in part, to the academic training of postdocs and researchers from abroad who are revitalizing our methodological outlook. Nevertheless, the de facto lack of Science Archaeology in Iberian universities greatly limits the speed with which change occurs.

Medieval Archaeology in Iberia is also defined by its atheoretical character, which is due, in turn, to the absence of debate regarding the construction of the archaeological record, and even to an explicit refusal to engage in theoretical reflection. The strong imprint of cultural historicism (which has marked the practice of "Visigothic archaeology"), an excessive dependency on the paradigms and concerns raised by the practitioners of medieval history, and the empiricism that in many occasions has led rescue archaeology, helps to explain this state of affairs. It is true, as has been pointed out here, that historical materialism and certain processual schools of thought enjoyed significant development in the 1980s and 1990s, with the creation of an archaeology of the state, and of the peasantry, although their influence has nowadays been severely limited. Post-processual approaches, on the other hand, continue to be a clear influence on the work of new researchers, although this tendency is in large measure determined by Anglo-Saxon trends. A critical reconsideration of how to interpret the archaeological records in its current context (characterized by the implosion of many post-processual schools of thought and the collapse of a particular way of doing archaeology in the light of the

developments of the last few decades) remains the fundamental challenge facing medieval archaeology in particular, and all archaeology in general.

In thematic terms, we can talk without exaggeration of a substantial research agenda, given that there are many projects currently underway. We do not yet have a detailed synthesis on the social and territorial transformations that took place in Portugal in the early Middle Ages, and this is in fact one of the few territories that C. Wickham did not include in his monumental work *Framing the Early Middle Ages*. Iberia remains, moreover, one of the most fertile territories of Europe when it comes to studying the process of state formation in the early Middle Ages, although we still lack a theoretical starting point and the empirical data with which to frame our analyses. We have sound studies at our disposal, as well as social theory, regarding the origins of the *andalusí* state, but analysis of the emergence of Asturian, Castilian, or Navarrese proto-state formations in northern areas, to cite only a few examples, is still underdeveloped. The study of the archaeology of centers of power is, undoubtedly, one of the best strategies to adopt as we continue to analyze these processes. Equally, the emergence of peasant communities that can be observed in large areas of Iberia between the fifth and eighth centuries contrasts markedly with the relative "silence" that characterizes other regions. Further to this, archaeology of the peasantry is allowing us to overcome the anachronistic ethnic approach that is still characteristic of the practice of "Visigothic archaeology."

Insofar as studies of *andalusí* society are concerned, one must concede that the high level of theoretical debate that had characterized research in the 1990s has now diminished as a result of the segmentation of research debates. Among the themes awaiting in-depth analysis, it would be useful to address the study of non-irrigated lands in the production processes of peasant communities, and the articulation of the city-*alquería* relationship; also useful would be intensive analyses of the inhabited and exploited spaces during the emiral and Caliphal periods, which might allow for the creation of analogies with insights which have already arisen from the study of urban centers.

There remains much to do with regard to the analysis of feudal societies. In diachronic terms, the study of the high Middle Ages (thirteenth to fifteenth centuries) continues to be penalized by an ingrained prejudice that has it that its greater wealth of written sources makes the use of archaeology unnecessary or too expensive, in spite of the fact that there exist urban records of great quality. For this reason, the focus of attention has fallen upon the study of the formation of feudal society in the high Middle Ages via the analysis of themes such as the formation of villages, the study of centers of power or the phenomenon of "*incastellamento*." The archaeological study of monastic lordships, the analysis of the forms of power over people and resources via the bioarchaeological record, research on grazing lands, or the extensive study of mountain areas through resources such as LiDAR are some of the themes in which work has begun and from which significant innovations may result in the next few years.

Moreover, another line of investigation which has been developing in recent years, although it has yet to be adequately systematized, is the archaeological analysis of minorities. For example, the archaeological study of Jewish settlements in Iberia now enjoys a great deal of evidential support, such as funerary sites at Montjuic (Barcelona) or Pamplona, Jewish quarters such as those of Lorca and Estella, or synagogues such as those of Alcudia at Elche, or Santa María la Blanca at Toledo. Nevertheless, we still lack adequate syntheses which go beyond empirical analyses to approach themes such as the exclusion and social articulation of these communities.

Iberian Mediterranean Basin: Rock Art

Inés Domingo Sanz
Departament de Prehistòria, Història Antiga i Arqueologia, ICREA/Universitat de Barcelona/SERP, Barcelona, Spain

Introduction

Under this designation, a list of 757 sites located in the Mediterranean side of the Iberian Peninsula was declared World Heritage in 1998, as "the largest group of rock-art sites anywhere in Europe," "providing an exceptional picture of human life in a seminal period of human cultural evolution" (Criterion III: http://whc.unesco.org/en/criteria/). Today the list has been updated and it includes more than 800 rock art sites.

The nomination refers to the main post-Paleolithic rock art tradition of this region, also known as Levantine rock art (LRA). Nevertheless the sites on the list also contain rock art motifs of two other major post-Paleolithic rock art traditions known as Macroschematic and Schematic rock art. To be consistent with the UNESCO declaration, this entry will focus on Levantine rock art.

Definition

LRA is one of the three main post-Paleolithic rock art traditions depicted in open-air sites located along the major river basins of the Mediterranean side of the Iberian Peninsula.

LRA was scientifically documented in 1903, several years after the discovery of Altamira Paleolithic paintings, when the Spanish archaeologist Juan Cabré discovered some naturalistic red deer at La Roca dels Moros site (Calapatá, Teruel). More than a 100 years later, the number of sites

Iberian Mediterranean Basin: Rock Art, Fig. 2 Main motifs depicted in Levantine rock art panels. (Photos by I. Domingo)

has significantly increased to expand along a wide region of the Mediterranean side of Spain: from the Pyrenees to Almeria (Fig. 1).

In a broad term the corpus of Levantine art includes mainly painted, and rarely engraved, motifs depicting naturalistic animals (deer, wild goat, bulls, wild boar, horses, insects, and so on), humans (male and female and occasionally children), and their equipment (bows, arrows, different sorts of bags or baskets, clothing and adornments, and so forth) (Fig. 2).

Contrary to Paleolithic rock art, where internal details are depicted (such as eyes, mouth, and animal coat), LRA artists chose to depict flat silhouettes with very fine and modelling strokes. The species and sometimes the sex (especially for humans and deer) are identified according to the characteristic profile of their silhouettes.

Breast, skirts, and wide pants are usually interpreted as female wear, whereas their absence or the presence of weapons (bows and arrows) is considered characteristic of males, even when the sex is not explicitly represented.

Compared to Paleolithic rock art, LRA uses an exiguous number of painting techniques: solid infill, parallel-line infill, contours, and single brushstroke. The colors used are mainly red, black, and white, with a significant prevalence of the former. In the last few decades, bichrome paintings and engravings have also been discovered, although these two techniques are still uncommon and restricted to a limited number of sites and regions (Domingo 2012a).

From the point of view of composition, LRA is mainly an art of scenes, although examples of

Iberian Mediterranean Basin: Rock Art, Fig. 3 Hunting scene (Cova dels Cavalls site, Valltorta Gorge, Castellón). (Martínez and Villaverde 2002)

other compositional patterns also occur, such as several known cases of exclusive and isolated bulls.

Key Issues/Current Debates/Future Directions/Examples

Despite more than one hundred years of research on this art, key issues such as the main subject matter, the chronology, the identity of the authors, and the sequence of this art still inform major ongoing discussions.

For decades LRA has been characterized as dealing primarily with hunting scenes (Fig. 3).

However, hunting scenes are but one among a wide variety of subject matters which include different sorts of social activities: warrior parades and conflicts, humans collecting honey, climbers, and maternity scenes. Furthermore, recent studies have demonstrated that the former representations of humans in LRA are not linked to hunting activities and that hunting scenes emerge only in the middle part of the sequence.

Chronology

LRA was originally dated to the Paleolithic and described as a regional variant of the Franco-Cantabrian rock art from Eastern Spain. However, in contrast to the Paleolithic cave art, LRA was depicted in open-air rockshelter sites. Similarly, while Paleolithic rock art mainly depicts naturalistic animals, LRA includes both naturalistic animals and dynamic human figures interacting in all sorts of narrative scenes. Currently, it is accepted that these significant differences between Paleolithic and LRA are not due to regional but chronological differences. Superimpositions of LRA over Macroschematic rock art, with parallels in Early Neolithic ceramic decorations, provide a minimum date for this tradition or at least for some of the chronological phases identified within this tradition (Martí and Hernández 1988). Thus, it is widely accepted that Levantine rock art was produced during the Neolithic. Whether the artists were the last local hunter-gatherers marking their landscapes as a response to the arrival of Early Neolithic farmers from the Middle East or they were the newly arrived farmers exploring and

Iberian Mediterranean Basin: Rock Art, Fig. 4 Humans change significantly along the sequence, starting with naturalistic figures (*left*) (Tortosilla rockshelter, Ayora, Valencia). (Photo by I. Domingo) and ending with small linear ones (*right*) (Cingle de la Mola Remigia rockshelter, Ares del Maestre, Castellón). (Photos by V. Villaverde)

Iberian Mediterranean Basin: Rock Art, Fig. 5 Evolution of subject matters according to the stylistic sequence of human figures (Domingo 2012b)

marking their new landscape to secure access to new resources is still under discussion (for a further discussion, see Marti and Juan-Cabanilles 2002; Martí 2003; Utrilla and Martínez 2007a; Cruz and Vicent 2007; Villaverde et al. 2012).

Sequence

LRA sites are palimpsests, with motifs and scenes of different styles and sizes gradually added to the same panels along different periods. Superimpositions and important variations in style, techniques, patterns of composition, and subject matter provide an order of styles, evidence of a complex and lasting tradition.

Contrary to human figures, the naturalism of animals remains more or less consistent throughout the Levantine sequence. Thus, humans are key to analysing the evolution of this rock art tradition.

Formal variations of humans from the Valltorta-Gasulla complex of sites show an evolution of at least five stages, starting with large, naturalistic humans, with body volume, accurate proportions, and all sorts of adornments (bracelets, bags, headdresses), and ending with small, schematic figures which lack body volume and which are out of proportion (Domingo 2005) (Fig. 4).

Similar schemas have been also defined in other Levantine territories, such as Aragón (Utrilla and Martínez 2007) or the High Lands of the Segura River (Mateo 2006).

These five stages also reflect certain thematic patterns within the Levantine sequence. Interestingly, there is an absence of hunting scenes in the initial stylistic episode, focused on different sorts of social activities (human parades, maternity scenes, wounded individuals, death scenes) (Fig. 5).

When hunting is depicted later on in the sequence, it starts from the specialized hunting of a deer. Only later in the sequence, we observe a broadening and diversification of the species (deer, wild boar, and wild goat). At the end of the sequence, both social and hunting activities are depicted but also other new themes such as scenes with people collecting honey and climbers.

In the same way, mapping the geographic distribution of specific motifs, techniques, or subject matters allows us to identify different schools or territorial behavior. For example, while bulls are especially significant in Castellón, Teruel, and Albacete provinces, wild boars are almost unique to "el Maestrazgo" (Domingo et al. 2003). So common traits do not mask regional specificities and different rhythms of change throughout the Levantine territory.

Thus, talking globally about LRA in the twenty-first century is to accept that a common tradition spread along a wide territory of the Iberian Peninsula, but time and the territorial behavior of the human groups caused gradual changes within this tradition.

Levantine rock art should be described as a network of artistic territories resulting from different rhythms of change and adaptation.

State of Knowledge and Current Debates

Introduction

Fish remains include bones, otoliths, teeth, and scales, but their analysis has been a comparatively recent development within zooarchaeological research. Given their generally small size and the large taxonomic diversity fishes exhibit, the late implementation of adequate retrieval techniques and a general lack of reference collections no doubt contributed to that effect. Fish studies provide crucial evidence to address a variety of paleocultural and paleoenvironmental issues and have more recently helped raise awareness about the importance of historical and prehistoric fish assemblages to contribute to the conservation and management of aquatic resources (Cleyet-Merle 1990; Wheeler and Jones 1989).

Definition

The analysis of fish remains from archaeological sites for the purposes of reconstructing material and nonmaterial aspects of past human societies and the paleoecology of former fish populations and aquatic environments.

Historical Background

The earliest studies of archaeological fishes were carried out by zoologists around the mid-nineteenth century. The papers by Hermann Schlegel on the fishes from medieval Dorestad (1842) and of Japetus Steenstrup on those from the Ertebølle culture, around 1850, are credited as the pioneer works. During the ensuing century, and except for work done on French Magdalenian sites (Sauvage 1875) and the review by Clark (1948) on prehistoric fishing in Europe, archaeological fish studies remained the *Cinderella* of zooarchaeology.

During the 1950s and 1960s, coinciding with the development of zooarchaeology, papers that one could label ichthyoarchaeological were mostly written by paleontologists and ichthyologists with scarce interest for anthropological issues. These studies dropped sharply after the 1970s and have always been of restricted value to archaeologists. The exception was Flannery's 1968 paper on the broad spectrum revolution, where fishes were taken as evidence for a broadening of the human predatory niche starting with the Upper Paleolithic.

The 1970s witnessed a profound change in this state of affairs. Largely through the efforts of scholars such as Jean Desse in France and of Johannes Lepiksaar in Sweden, fish remains became the focus of interest of archaeologically minded scientists. Casteel's 1976 handbook, mostly concerned with methodological issues, contributed further, but it was the birth of the Fish Remains Working Group in 1981 that helped to consolidate ichthyoarchaeology as a subdiscipline within zooarchaeology. The 19 meetings of the FRWG, held between 1981 and 2017,

Ichthyoarchaeology, Fig. 1 An overview of the interplay between techniques and research questions ichthyoarchaeological analyses help address (Taken from Jones and Richter 2017)

have insured a fostering of cooperation among scholars and constitute the yardsticks where new analytical tools have been introduced and ideas confronted. There are now well over 100 ichthyoarchaeologists in the world representing some 40 countries. These have proved instrumental for grounding fishes firmly within the theoretical framework of archaeological research programs (Fig. 1).

Key Issues/Current Debates

Retrieval and Sampling

Few fishes feature large bones, most remains reaching only to a few centimeters. Such contingency precludes an adequate retrieval by hand. Indeed, hand-collected samples produced the biases that lurk behind some of the old "paradigms," like Roman fish-salting installations being exclusively devoted to the processing of tunas or fishing in Denmark during the Mesolithic being just focused on pike.

Although sieving is necessary to insure an effective recovery of remains, and experiments have shown that species richness and diversity increase significantly when sediments are sifted through meshes of 3–1 mm (Zohar and Belmaker 2005), the decision as to what kind of mesh size to use will depend on the fishes one is likely to encounter, the type of sediment, and the state of preservation of the remains. Bødker-Enghoff (2005) evidenced that only a mesh size of 0.6 mm was capable of retrieving significant amounts of remains from the smallest fishes, as is the case of the smelt (*Osmerus eperlanus* L.). In general, ineffective retrieval of material can be ascertained through the high percentage of identifiable remains, a preponderance of the most robust elements (e.g., vertebrae), and their large average size.

Given the nonrandom distribution of remains that many fish assemblages exhibit, sampling constitutes a crucial issue. An appropriate sampling strategy requires knowledge of various kinds. During Roman times, for example, the processing of tunas on the beach where the animals were landed meant that most of the skeletal remains never reached the salting factory. If ever to gain knowledge about Roman tuna catches, the archaeologist should thus insure surveys of the coastal zones around those factories, to spot and eventually excavate such "fish cemeteries" along with the excavation of the site proper.

Further sampling considerations should be taken into account when molecular analyses are intended on fish assemblages. Aside from the sensible practice of selecting well-preserved specimens – preferably freshly excavated – an important issue is for some molecular analyses, in particular isotopes, to focus on taxonomically identified remains. Fish species, even closely related ones, exhibit quite different ecologies. Even specimens from the same species often exhibit different ecological preferences depending on their age, size, or sex. This generates different molecular signatures even for animals living in a similar environment. Although this has been obvious from the start in the case of terrestrial faunas, fish are sometimes pooled into loosely defined groups such as "marine/freshwater," etc. when the reality is far more complex. Freshwater input, continental shelf extension, habitat depth, and mobility are some of the variables that have a major impact on fish molecular analyses. For these analyses to yield meaningful results in fish, different specimens from each of the identified species need to be taken into account. Meaningful sampling can be accomplished by selecting right or left specimens in the case of the parasagittal bones, elements of different sizes, or specimens from different contexts.

Taphonomy

Taphonomic data are crucial to correctly frame the analysis and interpretation of an archaeological fish assemblage. Although at most inland sites man has traditionally been credited as the main accumulator of fish remains, such is not necessarily the case at coastal deposits. Many piscivorous animals, in particular marine birds, accumulate large numbers of fish remains (Erlandson and Moss 2001). Likewise, natural deaths, including episodic mortalities along a seashore or deaths resulting from the drying out of isolated pockets of water, are documented at both the local and regional scale to produce fish accumulations. Setting apart such "background faunas" from the archaeologically meaningful ones is far from straightforward and involves a combination of actualistic data (e.g., documenting those species of fish that suffer these episodes or are the targeted prey of certain predators), and taphonomical analyses proper, including microspatial studies of remains in situ, conditions of preservation, presence of articulated specimens, etc. Gnaw marks and traces of digestion often prove ambiguous, given their limited potential to yield species-specific signatures.

Fish taken by humans exhibit many kinds of manipulative marks. In general, biostratinomic (i.e., pre-burial) signatures, associated with angling, gutting, de-fleshing, or cooking, are not that frequent. Often, it is to post-consumption processes that the analyst turns in order to gain information about the history of the fish deposit. These processes include trampling, scavenger attack, and fossil diagenesis (i.e., post-burial events). Only in industrial settings, where large numbers of fishes undergo a similar mass processing, or in large fishes, where butchering often implies hacking, can the analyst find clear signs of how were fishes handled prior to consumption.

Analysis of the sediment may prove helpful in explaining the taxonomical and/or skeletal composition of a fish assemblage. Barrett (1995) reported that a pH of 8 was the threshold below which otoliths were unlikely to survive in a deposit. These kinds of data are more useful as predictors of survivability when combined with ethnographic and contextual information. There also exist biological phenomena that dictate differences. Ossification is very different in the two main groups of fishes (i.e., bony and cartilaginous) but also in the different elements of any given skeleton. Here, lipidograms may provide

rough blueprints as to what one may expect in terms of relative abundances. Idiosyncratic features, such as the calcium resorption taking place in the cranial bones of salmonids when in freshwater, have led to remarkable misinterpretations (i.e., the pseudo-hypothesis of salmons being beheaded). Such contingencies, along with others such as how rapidly remains were buried after discard or how active were the fungi and bacteria in a particular soil, create skeletal and taxonomic abundance profiles that have little to do with human behavior. Provided with the adequate tools, the analyst should nevertheless manage to "read in-between the lines."

In the case of the preservation of biomolecules on fish remains, the general practice is to apply the same criteria defined for other groups. Some authors have nevertheless raised concern on the impact of traditional collagen preservation criteria on fish samples that should be taken into account in the interpretation of data (Szpak 2011; Guiry et al. 2016a, b).

Identification

Some 95% of the bones in a fish skeleton are not diagnostic and most remains survive only as fragments. Even diagnostic elements exhibit such anatomical and taxonomic variability to render identification an extremely laborious task (Fig. 2). Identification of fish remains needs to be carried out with an adequate reference collection, but what adequate means is not always clear. Indeed, since the ranges of most marine species have experienced dramatic shifts in the past (Kettle et al. 2010) and many species have been traded over long distances, building up a reference collection often requires incorporating species not present in the particular area one intends to investigate. It also proves useful to incorporate specimens of different sizes from the same species, given that size implies morphological differences in certain elements. Reference collections for the purposes of ichthyoarchaeology are still uncommon in museums, and this has forced many analysts to build up their own collections.

No practical alternative exists for the reference collection. Atlases and equivalent publications are rare and often not that useful, except perhaps for the experienced analyst. There exist logistic reasons for this being so (e.g., the impossibility of providing a comprehensive survey of taxa and elements), but more often these reasons have to do with practical considerations (e.g., fragments are never depicted). Fish bone morphology is a size-dependent variable so that one species may exhibit different morphologies with different sizes. This is a general phenomenon for vertebrates that grow throughout their life. In other instances, closely related species exhibit diagnostic morphologies only above a certain size threshold so that identification of juveniles only proceeds down to the level of genus or family. These taxonomic categories often prove far too coarse to provide data of interest, given the marked differences at the level of diet, distribution, and behavior that closely related species exhibit.

Among the alternative identification methods, frontal X-radiographs of vertebrae have proved of value in some cases (e.g., salmonids, gadids), less so in others (e.g., catfishes, characids). Radiographs are also impractical for reasons having to do with logistics and safety. For these reasons, they have been essentially abandoned although from time to time they resurface at the front line of research.

Current genetic methods enable highly specific identification from modern fish, yet ancient DNA fish studies are still lagging in development when compared with other vertebrates despite them having provided spectacular results in certain groups (Yang et al. 2004). Taxonomic diversity partly explains such state of affairs, as does the porous nature of fish bones that facilitates "drainage" of molecules into the sediment. Another major drawback is that, due to the conditions of preservation on many sites, success rates of fish DNA recovery are usually low (i.e., 2–5%). Although aDNA is not a viable alternative to osteology, it may often help address issues where the precise identification of certain remains could be of great relevance. Such would be the case of genetic traits not recorded on the skeletal elements that reveal the genetic structure and phylogeography of former fish populations.

Ichthyoarchaeology, Fig. 2 (continued)

One promising technique of taxonomic identification is the "molecular barcode" of the bone collagen protein. *Zooarchaeology by Mass Spectrometry* (ZooMS) measures the differences between peptide masses in the collagen protein through mass spectrometry, identifying fish species in much the same way as DNA fingerprinting does (Collins et al. 2009; Richter et al. 2011). Given that sequences can be rapidly and cheaply identified, that collagen persists in most zooarchaeological samples, that the analyses require only a few milligrams, and that the specificities of its signatures are highly diagnostic, ZooMS should witness an explosive development in the not too distant future. Likewise, and given that presently only a few fish species have been fingerprinted, an important effort is devoted to enlarge the reference collections with fish taxa of archaeological relevance (K. Korzow-Richter and M. Collins, verb.com.).

Estimating Abundance and Importance

Of the major estimators of abundance, only the NISP (i.e., the number of identified specimens) and the MNI (i.e., the minimum number of individuals) have been regularly used by ichthyoarchaeologists. Given the large differences in the total number of elements among the various groups (i.e., vertebral counts range from 24 to 150), and that some species have a far larger number of diagnostic elements than others (up to 500 species-specific spines in the case of some porcupine fishes), the MNI or its equivalent alternatives, such as the MNE (i.e., the minimum number of elements), are to be preferred to the NISP. But this is only possible when samples are of a reasonable size (i.e., $\geq$500). When collections are small, interdependence presumably becomes less of a problem, and use of the MNI deflates specimen counts to ludicrously low values. Under such circumstances, analysts often turn to the NISP despite all of its inherent weaknesses.

Numerical abundance is but one way of assessing importance. Another estimator of importance is weight, often far too variable on most fishes to prove of help. Cultural indicators of importance, such as food avoidance behaviors, alternative names given to a particular species, or the prices species command on the market, depend on the availability of ethnographic and documentary records, neither of which proceed much beyond Classical Antiquity. In the case of fishes, one should also stress that social importance is not necessarily a reflection of economic importance, many species being esteemed only on account of their rarity, large size, or some extraordinary feature (e.g., poison).

An indirect way to address fish abundance, and occasionally importance, in archaeological fish assemblages is through molecular analyses. In this way, identification of osteomorphologically indistinguishable, closely related species can shed light upon the main targets of exploitation within a given species pool and contrast past to recent abundance of certain species as demonstrated for American salmonids (Speller et al. 2005). Still, the major contribution to former abundance estimation will come through population genetics studies allowing one to detect, among others, gene flow (bottlenecks) and genetic drift events linked with environmental and biogeographical phenomena as well as with human exploitation.

Size Estimation

The size of fishes provides crucial information not only about human choice, fishing technology, and selective behavior but often about the environment from where the fish assemblage was harvested.

Given that fishes grow throughout life, fish size reconstruction is a valuable provider of information in ichthyoarchaeological studies. The method rests on the relationship that exists between a particular dimension of a bone and the various lengths

Ichthyoarchaeology, Fig. 2 Hyomandibular bones of Mediterranean sea breams (Sparidae) and a grunt (Haemulidae, *lower right*). Although most of the diagnostic fish bones are quite easy to assign to family or even to genus level, assignal to species relies on very subtle differences that are often lost in the fragmented bones one retrieves in archaeological deposits (Taken from Roselló 1989)

(i.e., standard, fork, or total) of the animal. Matching archaeological specimens with their equivalents of known body size, either visually or through measurements, is the most straightforward procedure but requires large reference collections. The absence of precise equivalents renders the method unfeasible or turns it into a risky exercise of extrapolation. Another alternative is the power curve equation, using the least squares regression or an equivalent method. This one does by plotting specific bone measurements from specimens of known size against the original fish length. This is a laborious method requiring the preparation of a large number of specimens covering the whole size range of a species. This is not an easy task nowadays in the case of the largest animals. Regression equations describing such relationship are available for most of the main bones from most of the archaeologically relevant species. Large numbers of archaeological bone measurements can thus be converted into estimates of length, and these in turn used to calculate statistical parameters, such as the mean and standard deviation. These data provide the basis for reconstructing the size-frequency histogram, which represents the prehistoric fish catch (Fig. 3). One should stress that isolated values here only represent estimations. For such reason, it is advisable to allocate them within size classes that, depending on the size of the species, range from less than 1 to more than 10 cm.

The estimation of weight follows the same procedures as those of size but is far less accurate since depending on their condition, the time of the year, etc., fishes of identical size can have very different weights. Weight-frequency histograms

Ichthyoarchaeology, Fig. 3 Upper: Size-frequency histogram of barracouta (*Thyrsites atun*) fork lengths from the site of Long Beach (Otago, New Zealand) based on 15,558 bones. Lower: A modern trawled catch of barracouta from New Zealand. These data indicate that the prehistoric catch targeted only the largest specimens of the population (Taken from Leach 2006)

thus build on weight classes with far larger ranges than those for size.

Seasonality

Fish remains can presumably document whether a site was occupied on a permanent or a seasonal basis. However, in most cases, what the analyst manages to reconstruct is the scheduling in the catch of this specific sector within the overall animal exploitation strategy. This is possible because fishing is often a seasonal practice modulated by the migration of species during a particular time of the year, or the restriction, for human populations in the past, of marine navigation to the spring and summer months.

Seasonality is alternatively documented by the presence of certain species and the size distribution of the archaeological population and through skeletochronological techniques. These procedures rest upon actualistic studies that require a sound knowledge of the biology of the animals and how this changes from place to place (Fig. 4). Only well-dated levels, representing short-lived episodes, are likely to provide clear seasonal signatures as these tend to fade away when levels represent pooled averages from a wealth of episodic and non-episodic fishing events.

Seasonal fishing is exemplified by the presence of anadromous fishes, such as salmon and sturgeons, at inland sites. Equally informative are marine fishes such as sardines (*Sardina* sp.) and tunas (*Thunnus* sp.) that approach the shore to spawn with the onset of spring or summer. The best "bioindicators" are those species appearing only during a very short time (e.g., 1 or 2 weeks), such as the smelt. In general, the higher the latitude, the more concentrated the presence and the more reliable "bioindicators" are. The analyst only needs to insure that local fishing, not import, has been the reason for that presence. To this end, skeletal spectra, evidencing the presence of complete specimens, often prove helpful.

When fishing is conducted on a nonseasonal basis, fishes of many different sizes within the same species stand a chance of being collected. This creates a bell-shaped distribution of size classes (i.e., age groups or cohorts) devoid of marked peaks. Seasonal fishing, on the other hand, tends to concentrate on specific cohorts, producing size class histograms with

Ichthyoarchaeology, Fig. 4 The seasonal pattern of barracouta catches in New Zealand waters today. These maps provide the baseline to decide whether a particular coastal site was occupied at a specific time of the year or not (Taken from Leach 2006)

discrete peaks of abundance (i.e., non-normal distributions).

Within the realm of ichthyoarchaeology, skeletochronology, the study of the growth rings produced by organic structures, also aims at determining the moment of capture. Given that one can only assess this through the thickness of the last (i.e., outermost) growth ring, and that most archaeological specimens are eroded on their margins, the method is often of restricted value. These estimations also suffer from the small sample size that most archaeological collections exhibit and from a lack of comparative baseline data on modern samples to validate results. The few analyses carried out on modern otoliths evidence that the timing of the seasonal changes in the edges of these calcareous concretions is extremely variable, so that data from just one or very few elements is useless as a seasonality indicator. The fact that modern populations of the same species are subjected to different deposition patterns of the opaque/translucent layers adds far more uncertainty given that no reliable analogues exist for the archaeological populations. This methodology improves when combined with isotopic analyses of the otolith that provide further insights on seasonality. Measuring oxygen isotopic ratios along the growth increments allows one to more precisely define the season of capture (Hufthammer et al. 2010). The method is, alas, restricted to species that experience seasonal temperature fluctuations. Indeed, even on large archaeological assemblages, determining seasonality is impossible when the fishes were not captured during their period of fast growth. Given all these limitations, it should come as no surprise that skeletochronology is no routine procedure in ichthyoarchaeological research.

Trade and Processing

Throughout the Paleolithic and Mesolithic, the long-standing paradigm maintains that fishes were consumed either on or close to the spot they were fished. Although fish meat spoils fast when unprocessed, fresh fishes can still safely travel 25–30 km inland in a day and remain edible. The archaeological record evidences that prior to the Neolithic, non-local fishes are regular items in sites lying at short distances from the shore. The village of Dalma in SE Arabia (5000 BC) has been postulated to represent the earliest fish processing center in the world (Beech 2004). The earliest evidences of marine fishes transported far inland in this area date from the Iron Age (Rafaq, Oman peninsula first millennium BC), and it is from around this time that the first unequivocal evidences of long-distance fish trade (i.e., remains in amphorae) appear in the Mediterranean. Such trade has been often postulated to constitute a side effect of surpluses that resulted from improvements in fish catching methods (e.g., boats, seine nets) and methods for meat preservation (e.g., oil and vinegar). But preservation by drying, salting, or even smoking must have far deeper roots in time if one is to believe ethnographic data. The consensus nowadays thus concedes that there might exist additional, more complex socioeconomic reasons linked to human demography, such as the emergence of empires, regional markets, etc., that fostered such developments at a given time and place. But conclusive evidence on this subject is still scarce.

Once fish trade becomes firmly established, fish assemblages deriving from subsistence fishing need to be set apart from those resulting from fishing for export. Although no single signature suffices to set apart the two groups, the combined use of the estimators of abundance and species diversities (higher in "subsistence sites"), a balanced skeletal representation in subsistence settings that tends to be skewed in industrial settings (i.e., the "heads stay *vs.* tails travel" model of cod trade circuits; Perdikaris 1996), and a normal distribution of sizes (subsistence) versus clusterings around a single size (export) often allow the analyst to decide this. At sites where commercial fishing for export was practiced, one often finds highly standardized treatments of the fishes. These may involve cut-marks on the same portion of a particular element or the removal of some diagnostic portions of the skeleton as was often the case of the head in traded cod and the pectoral girdle in herring that were gutted prior to salting.

Molecular methods have more recently allowed ichthyoarchaeologists to reveal the provenience of specific fish remains. Polymorphisms on the mtDNA control region of the catfish *Clarias gariepinus* (Burchell 1822), for example, define regional haplotypes that have allowed analysts to determine that imports of this catfish into the Turkish city of Sagalassos originated on the Lower Nile (Arnt et al. 2003). Working on carp (*Cyprinus carpio* L.) teeth from this same site, Dufour et al. (2007) used stable isotope signatures ($\delta^{18}O$, $^{87}Sr/^{86}Sr$) to explore the origin of this intensively consumed fish during the Early Byzantine period to reconstruct trade networks. Using carbon and nitrogen stable isotope analyses of cod (*Gadus morhua* L.) populations from the NE Atlantic, Barrett and collaborators managed to not only reveal the provenience of specific bones on different sites but also to determine that the onset of long-distance trade for the species did not start until the thirteenth century AD (Barrett et al. 2011).

Fish Catching Methods

Fish catching methods can rarely be inferred from the fish assemblage because many species can be taken in a variety of ways (i.e., the problem of equifinality), whereas a hook of a given size and shape can take a large number of species (Morales 2010; Fig. 5a). Fishing gear provides less ambiguous information, but, except for items such as weights and hooks, executed on stone and metals, tackle made from perishable plant fibers is often lost. This would also be the case when fishes were captured with poison. Even when present, some gear might be easily missed for lack on an appropriate analogue (Fig. 5b). It is for such reasons that documentary and ethnographic records often prove instrumental for a correct interpretation of the evidence.

Occasionally, one is able to spot shifts in the fishing strategy through changes in the diversity of species or their size distribution. As a rule, people started to fish on shallow waters and later

Ichthyoarchaeology, Fig. 5 (**a**) Identical gear, such as similar-sized hooks, allows people to fish a variety of size classes from many different species (Taken from Morales 2010). (**b**) The halibut hook (upper) and the herring raker (middle, bottom) were tackle used by the NW Pacific Indians that combined perishable (wood) and nonperishable (flint microliths) materials. Given that no present analogues for them exist today, archaeologists retrieving loose microliths in archaeological deposits would be incapable of inferring from them the existence of such specialized fishing. Drawings by A. Morales Muñiz inspired in artwork depicted in Stewart (1977)

Ichthyoarchaeology, Fig. 6 The development of fishing in the Nile witnessed an early stage when species that inhabit the more readily accessible waters of the floodplain, such as the catfish, *Clarias gariepinus* (black circle), were preferentially taken. Later, as fishing technology and navigation improved, species inhabiting the main river channel, such as the Nile perch, *Lates niloticus* (white circle), are recorded in far greater numbers in the deposits (Taken, with modifications, from Van Neer 2004)

moved to less accessible zones. In the prehistoric Mediterranean, the long-standing paradigm held that the most littoral taxa, such as the groupers (Serranidae) and sea breams (Sparidae), were targeted previous to the Neolithic and offshore taxa, such as clupeids and scombrids, came later (Fig. 6). The paradigm also holds that improvements in fishing and navigation technology produced an increase in the number of fish taxa with time, but the data tell a different story. Indeed, recent syntheses evidence that at well-excavated Paleolithic sites, not only were fish diversities as high as or even higher than those from later time sites but also that early assemblages regularly incorporated small, offshore fishes such as clupeiforms (Morales Muñiz and Roselló Izquierdo 2016). New data are needed to settle this issue.

Cultural Issues

Nonmaterial aspects of human-fish relationships proceed beyond the simple equation "animal equal meat," but being dictated by complex epiphenomena for which analogical frames of reference are often lacking, most of these issues are difficult to address. Ethnographic, ethnohistorical, and – in the more recent periods – documentary data provide frames that allow ichthyoarchaeologists to proceed beyond strictly actualistic models often skewed toward modern, western-centered standards. The three major conceptual domains archaeological fish assemblages help address refer to status, ethnicity, and symbolism.

Ichthyoarchaeologists often make use of fish bones to infer the status of people that inhabited a particular site. Without reliable knowledge of consumer preferences, alas, even for collections where context is well documented, social class assignment can be risky. In this way, although the distinction of fishes for the rich ("feasting") and for the poor ("fasting") is routine in archaeology, and although historic sources indicate that, at least in Europe, the rich preferred fresh, rare, and large fish, matters are often not so straightforward. One traditional indicator of high status, for example, is the presence of fishes imported from distant lands. Recent research on the subject, while not denying that possibility, stresses the need to be careful with simplistic interpretations given that products such as the lower-quality fish sauces of the Roman world or processed herring in medieval Europe were readily accessible to all levels of society (Van Neer and Ervynck 2004). On methodological grounds many problems remain. In this way, even within the same manor, fish remains eaten by the rich, and those eaten by their servants often ended up in the same dumpyard, making it difficult to know who ate what. Documentary data reveal other limitations such as the "rich/poor" dichotomy, itself being a

poor reflection of social class and status, the division of consumers being often far more refined. In the Netherlands and Flanders during the Modern Age, for example, no less than seven social groups were recognized of account of the fish consumed (Bennema and Rijnsdorp 2015). Those documents reveal quite distinctive fish consumption practices within the poor classes depending on whether these were fishermen or not and also that skippers and their families (i.e., middle classes) were the ones consuming rare species that were (sic.) "*too good for the rich and wealthy*" (Bennema and Rijnsdorp 2015). Similar problems are faced by analyses aimed at spotting differences in the diet and the use of space according to gender or age within a given social/economic group. These studies are still scarce despite ample ethnographic and actualistic data highlighting the role women played on activities such as fixing the nets, preparing fish for consumption, etc. (Insoll 2001). Clearly, a lot of idiosyncrasy is inherent to any fish assemblage when considered from a social standpoint, and a lot of work lies ahead if one ever wants these issues to become meaningful and productive routines for ichthyoarchaeologists.

From a strictly biogeographical perspective, the sheer taxonomic diversity of fishes from any given area confers fish assemblages a *regional signature* (i.e., ethnicity, in a rather loose sense of the term) that, depending on its specificity, may prove of help to explore phenomena such as provenience and trade. Such would be the case for the lands of the Roman Empire of the three groups associated with the Roman commercial fisheries (i.e., bluefin, *Thunnus thynnus* L., mackerels *Scomber* sp. and sardine) and of cod and herring (*Clupea harengus* L.) in the NE Atlantic from the medieval period onward. Occasionally, such signatures can be quite restricted. Starting with the third century AD, the Roman provinces bordering the North Sea developed their own fish sauces from local species such as the smelt and sprat (*Sprattus sprattus* L.) that were absent or rare in the Mediterranean (Van Neer and Lentacker 1994).

The clearest instances of ethnicity sensu stricto are inferred on fish deposits when food taboos and religious practices modulate consumption. In many societies, from the Vikings to the Maoris, eels were taboo because of scavenging on drowned people. In medieval Iberia, *Haram/makruk* (forbidden/unclean) fish, with snake-shaped bodies or with bodies devoid of scales, and specific ways of filleting fish, allow analysts to typify deposits as Christian or Islamic (Morales Muñiz et al. 2011). These same fishes are non-*kosher* for Jews, and Jewish deposits in European cities have been also recognized for their absence of non-*kosher* taxa. Matters become complicated when fishes from different communities end up in the same deposit and also when people exhibit a wide range of tolerance to feeding precepts.

Symbolism is undoubtedly the most difficult cultural aspect to address with archaeological animal remains, and fish constitute no exception to the rule. Because of the inherent variability on how each group categorizes fish species, neither ethnographic nor ethnohistorical and archaeological data, taken in isolation or combined, constitute a guarantee to correctly interpret fish assemblages from a symbolic standpoint. Not surprisingly, the scarce studies thus far available concentrate on one or very few fish categories and deal with data that reach into times where ethnographic and ethnohistoric analogues may prove relevant. Peres and Deter-Wolf (2016) have ethnohistorically reinterpreted the use of garfish (Lepisosteidae) by the American Southeast Indians evidencing that these fishes were variously used for making ritual tools (sacred bundles), totems, and talismans and for scratching and tattooing bodies or as items for votive deposits, builder's rites, etc. Flesh was considered of poor quality and often discarded. The traditional archaeological interpretation of associating their remains with feasting events is thus probably misfocused and in need of a revision. Aboriginal cultures deeply associated with the sea as Polynesians, Aleuts, and Northwest Pacific Indians have a wealth of legends, myths, and uses for fish that transcend material aspects. Even in these cases, a correct symbolic interpretation of fish assemblages would call upon for more archaeological context than that normally documented on hunter-gatherer sites.

International Perspectives

From total neglect to full integration into archaeological research, a series of "methodological stages" can be defined in the development of ichthyoarchaeological research for any given area on the basis of output. Interest in fishes without the implementation of the adequate retrieval methods, for example, results in extremely poor and heavily biased samples of scarce scientific value where fish remains often are listed as "*Pisces* indet.." Once the problem of retrieval is solved, the lack or inadequacy of the reference collection is manifested in that bone reports can rarely proceed beyond the level of family, being thus of rather restricted value. This stage often corresponds with areas where the potential number of ichthyoarchaeologically meaningful species is high (e.g., coral reefs, tropical freshwaters) and many are osteologically difficult to set apart from each other. Only when fine retrieval produces large, contextually and temporally well-defined, samples and a good reference collection is at hand, can the full potential of ichthyoarchaeological research come to effect. As of this writing, despite the explosive development of ichthyoarchaeology in certain areas of Central and South America or the South Pacific, there still remain huge pockets of unexplored territory, mostly in tropical Asia and Africa.

From a geographical standpoint, the search for patterns that integrate data into regional models is feasible only once the number of sound, local, studies reaches a certain threshold. Very few areas in the world, mostly in the temperate latitudes, have reached such a level of integration. As regional trends emerge throughout the world, one could foresee a time when these would merge into an all-encompassing worldwide picture. This would allow for a better framing of variability from both the vertical (i.e., temporal) and horizontal (i.e., spatial) standpoints. Researchers would then be in a more adequate position to explore how the interaction between fish populations and people contributed to shape both human evolution and that of aquatic environments.

An apparently secondary, yet crucial, issue this development of ichthyoarchaeology on a progressively global scale raises is that of nomenclature. Indeed, the inertia on many publications from the English-speaking countries has been to concede preference to common names over scientific ones. Such practice is not too troublesome when papers refer to fishes from ichthyologically well-known regions, such as Western Europe or North America where most species have a common name in most languages. In ichthyologically worse documented regions, often coinciding with areas of high fish diversity, as is the case of the Amazon basin, China, etc., most fishes do not have a common name, or if they do, this is often in a local language that scholars are unacquainted with. The use of generic names such as "grunts," "snappers," etc. does not help either because these can refer to different taxa in different countries, even English-speaking ones. For these reasons, ichthyoarchaeological publications need to provide the scientific names of the taxa they report.

Future Directions

Ichthyoarchaeology has been traditionally addressing archaeological questions, and it seems that it will go on that way in the future. However, fish remains from archaeological sites represent an important source of knowledge for researchers in the Life Sciences, and it will only be a matter of time before a systematic collaboration between the two fields emerges. Researchers and policy makers in the Life Sciences require adequate baselines to issue guidelines for the appropriate conservation of species and a sustainable use of resources. The research likely to emerge from that collaboration would benefit from the fact that ichthyoarchaeology has the potential for providing a far deeper time scale, thus baselines closer to the original (i.e., "pristine") conditions, than the time frame available for researchers and policy makers thus far.

One field where ichthyoarchaeology has already made some progress is that of ***Fisheries Research***. Fishing by humans represents a new kind of pressure on fish populations, and determining since when and how have these pressures been exerted and how have fishes responded to them constitute largely unexplored, yet promising fields of research. The baselines for studying these phenomena are mostly drawn from data and

models from fisheries biology. Given that systematic catch statistics are only available for the past century or so, many of these contributions focus on determining the antiquity of intensive exploitation of commercial stocks. Large-scale fishing has been loosely documented throughout the Mediterranean since ca. 1000 BC, but the work by Barrett et al. (2004) has been the first to demonstrate that in England the clearest changes in marine fishing occurred rapidly around AD 1000 (i.e., the so-called Fish Event Horizon) and that these involved substantive increases in the catches of cod and herring. Still, most of these studies do not often proceed beyond qualitative terms (Fig. 7). In order to address the impact of past fisheries quantitatively, large numbers of well-excavated, primary deposits, covering the appropriate time intervals and featuring large assemblages of fishes, will be required. These assemblages should produce high-resolution catch composition if they are able to provide statistically relevant data about size ranges and other biological parameters such as sex (Fig. 8). In the meantime, historical studies of fish landings and catching effort (Øiestad 1994, Jackson et al. 2001, see also papers on issue no. 87 of *Fisheries Research* 2007) are already providing a broader perspective of human impact on fisheries.

Even though the intensification of fishing spelled disaster for some species, fishing is not the only way through which humans have shaped fish abundances and distributions in the past. Pollution, habitat degradation, civil engineering works, or even species translocations may have had more pervasive effects not only on fish populations over time but, more importantly, on the aquatic food-web structure that supported them. For such reasons, a second area where ichthyoarchaeology is likely to make a meaningful contribution to the Life Sciences is that of **Conservation** (Rick and Erlandson 2008). Some historical ecology researchers have addressed topics such as the contamination of freshwater bodies or the impact of watermills on salmon

Ichthyoarchaeology, Fig. 7 "Fishing down the food web" is a popular theory on the development of fishing that has lately gained ground within ichthyoarchaeologists. This hypothesis maintains that, in the "pristine" environments of the Upper Paleolithic, people tended to concentrate their fishing on large, predatory, fishes such as the salmons and the groupers (black circle; condition depicted in (**a**), and as these stocks became (locally) depleted, they (progressively) turned to species lower down the food chain, thus more abundant (white and gray circles; conditions depicted in **b**, **c**, and **d**). While there exists historical evidence testifying to the validity of some of these postulates, it is equally true that the idiosyncratic variability most sites exhibit demonstrates that there is a lot more to species shifts in the past than a mere human-dictated directional trend and also that absences of small-sized species at the base of the food chain (light gray) may even represent instances of not sieving with the appropriate mesh size

Ichthyoarchaeology, Fig. 8 Many fish species change sex as they grow. In protandrous species – i.e., those where males turn into females after reaching a particular size (dotted line) – a systematic removal of the largest specimens can have dramatic consequences for the viability of the stocks unless the animals are able to accommodate their ontogeny to the fishing pressures

populations (e.g., Hoffmann 1996; Lenders et al. 2016). Some of these changes have been recorded in the archaeological record, either as faunal turnovers, such as that of pollution-tolerant eels and cyprinids replacing salmonids in the rivers crossing past Middle Age cities in Europe, or through local extinctions of species such as Atlantic salmon (*Salmo salar* L.). These data are providing a broader perspective of human impact on aquatic environments, yet seldom have they been of use in fish habitat restoration efforts though the few contributions in this field look promising (Butler 2011). Isotopic analysis have proved useful in reporting anthropic effects – organic pollution, deforestation, fertilizers, etc. – in both freshwater and marine ecosystems (Dufour et al. 2007; Fuller et al. 2012; Häberle et al. 2016). These studies have also clarified a wealth of secondary issues such as the nonmigratory nature of the Atlantic salmon from Lake Ontario in the past (Guiry et al. 2016b).

The consequences of human fishing pressure on past stocks such as the impact on food webs remain unexplored. The rigorous approach of Braje et al. (2017), combining the study of size reduction and nitrogen ratios from bulk collagen isotopic analysis through time, paves the way on how can ichthyoarchaeology be used to create historical baselines for present-day fisheries and conservation research studies. Another fruitful line of research revolves around the fishing-down-the-food-web proposal (Pauly et al. 1998; Fig. 7). Compound-specific isotope analysis (CSIA) of nitrogen stable isotopes ($\delta^{15}N$) offers a method to address longer-term disruptions in aquatic food webs in order to assess the nature and intensity of "top-down" effects such as overfishing and "bottom-up" effects such as climate change and pollution. This technique focuses on individual organisms and species, not requiring the sampling of organisms from other trophic levels that the bulk isotope approach demands. Despite it being a recent application in archaeology, CSIA allows trophic level to be more accurately estimated and may emerge as a powerful tool to explore the structure of pristine fisheries and their evolution through time.

One major problem most fish collections exhibit is their small size. This often precludes the application of quantitative techniques and obtaining consistent patterns. Likewise, for syntheses to prove of value, large volumes of

cumulative data are needed. Meta-analysis (i.e., analyzing data pooled together in chronological and spatially meaningful ways) is one way of doing so and an area where future developments in ichthyoarchaeological research are likely to take place (analytical packages, such as *archSeries* being already freely available on the Internet). In a seminal contribution on the fish remains from urban London, meta-analyses allowed Orton et al. (2017) to evidence that the sudden onset of marine fishing, the aforementioned Fish Event Horizon, predated any visible decline in deposition of freshwater fish, thus could not have been driven, as has been suggested, by a previous depletion of inland fisheries.

From the standpoint of methods, the explosion that is taking place in the discipline will involve the mass deployment of **molecular techniques**, including stable isotopes, DNA, collagen, and geochemical analyses. Such deployment will not only allow for the identification of many otherwise unidentifiable remains but also help in the resolution of past biogeographic patterns and the recent evolution of fish populations. Still, in the case of stable isotope analyses, while the factors affecting the C and N isotopic values are fairly well understood, their interaction is still far from clear. A better understanding of these interactions, and how specific factors play out in isotope values across former aquatic ecosystems, would greatly enhance the value of isotope studies in ichthyoarchaeology. In general, we have seen that molecular techniques are being applied to archaeological fish remains at a far lower pace than is the case for other vertebrates. The difficulties one needs to circumvent in order to change such state of affairs can be grouped into four categories:

1. Diversity: Paleogenetic studies require genetic/genomic libraries (sequences of reference), thus a previous and intensive research effort to fingerprint modern specimens. This is a slow process in the case of speciose groups that restricts the explanatory power of the analyses thus far published. Mitochondrial analyses are not often very effective on many fish species given the mobility and admixture their populations exhibit. Lastly, only a small proportion of fish taxa have been genomically studied. This restricts the range of target species to incorporate into archaeological studies and demands for specific genetic programs to be incorporated to archaeological projects, something not always understood on the part of project evaluators.
2. Size: Given that some molecular analyses require a large amount of bone in order to be successful, the generally small size of fish skeletal elements even makes it difficult to insure reliable extractions.
3. Histology: The singular mineral and protein structure of fish bone affects preservation, thus the success of conventional retrieval and extraction protocols developed for terrestrial vertebrates. Protocols need to accommodate to fish tissues to insure success, a slow and time-consuming process (Szpak 2011; Guiry et al. 2016a).
4. Ichthyoarchaeologists: Specialists play an instrumental role in fostering research. Among others, a successful molecular analysis on fishes should start with a clear ichthyoarchaeological question, the evaluation on what method could yield better information or key data, and most importantly, a selection of well-preserved samples from meaningful sites/contexts/levels. As of this writing, many ichthyoarchaeologists are not knowledgeable in these areas, and their collaboration with molecular archaeologists has been slight.

In terms of conventional identifications, online atlases, such as that available at the Archaeological Fish Resource site (http://fishbone.nottingham.ac.uk), though still in an incipient stage, are bound to become essential tools. One can foresee a time, as digitized images allow for the rotation of the elements, incorporate fragments and bones from fishes with different sizes, etc. when digital atlases will take the place of the conventional reference collection. This would enhance the labor of researchers in the field and of those forced to identify samples in their countries of origin.

One final tool to carry out identifications is that of Geometric Morphometrics (the quantitative

analysis of form, a concept that encompasses size and shape). Although GM may be of restricted use to set apart similarly looking bones from different species, it may nevertheless prove more useful in describing ontogenetic changes (developmental changes in form) taking place within bones from the same species. One hopes that future developments within GM are likely to come out with solutions to long-standing problems of identification of fish remains.

Iconography in the Roman World

Matteo Cadario
Dipartimento di Scienza dell'Antichità, Sezione di Archeologia, Università degli Studi di Milano, Milan, Italy

Introduction

The Roman world was populated by images. They could be encountered everywhere, in both public and private areas, as decorative aspects of buildings or decorations on individual objects, during shows, and on enduring monuments. These images carried political, cultural, and ethical messages that were relevant for the public discourse, which promoted in a propagandistic way values that were depicted as building blocks of the collective identity. They were also relevant for the private discourse for their contribution to the illustration of the personal interests of owners and consumers. The Roman culture was a visual culture, the interaction between image and spectator was very close, and images were one of the most direct and efficient communication channels.

Definition

For this entry, we have chosen to consider as "Roman iconography" the ensemble of images and figurative representations that were popular in the Roman world of the Republican and Imperial periods. The use of a more specific definition to narrow the investigation to topics considered more authentically Roman, in other words without immediate and recognizable Greek precedents (state-level ceremonies and portraiture), would be misleading. In fact it is very difficult to draw a distinction between the two iconographic traditions; it would be impossible to reconstruct the imaginary of an era and its political, cultural, and social evolution. Nevertheless, the studies of Paul Zanker on the creation of the new visual language in the Augustan period constitute an exemplary body of work (Zanker 1987).

When we deal with iconography in the Roman world, we have to face the problem of the close relationship between reality and representation, the key role of images in the preservation of memories related to an event or a person, the indissoluble connection between an image and its model, and the ability to recreate the illusion of the presence of a person by means of a static statue. Consequently, an image could evoke strong reactions in spectators (Gregory 1994). The power of the image widens beyond its religious and propagandistic meaning, as demonstrated by the various ways in which images have been condemned in the Roman society. Here we can recall the sanctions against memory (referred to by scholars as *damnatio memoriae*) imposed on the names and images of unpopular emperors, disgraced family members, and usurpers for reasons of politics and ideology (Varner 2004).

Romans themselves were conscious of the importance of images in their society; the Greco-Roman culture of the Imperial period focused its attention on the meaning of images with the conviction that they covered a role of primary importance for the *paideia*. The idea that the role of imagination (*phantasia*) could bring the artist closer to the poet was shared by intellectuals. The description of images (*ekphrasis*) became an autonomous genre in the second century BCE; several authors adopted it as their subject such as Philostratus the Elder and Philostratus the Younger and Callistratus. Their works offer a very

interesting summary of ancient iconographic and iconological thought and of its exegetic methodology (Abbondanza 2008).

Another important field of investigation is the ancient reaction to pantomime and the meaning of the mythological *tableaux vivant* performed by dancers: Plutarch, Lucian, and most of all Libanius (*Orationes* 64.118) have in fact described the connection between pantomime and images, granted by the analogy between durable iconographies, represented through monuments, buildings and objects, and ephemeral iconographies, visible at theatrical performances, rituals, and public ceremonies.

Key Issues

A Ceremony That Generates Images: The Triumph

In public art, the interaction between the reality of state's ceremonies and their idealized representation was constant as we can deduce by a brief analysis of the triumph, a ceremony capable of generating a wide iconographic repertoire (La Rocca and Tortorella 2008). The triumph itself was a sumptuous and multimedia scenographic show; images had a prominent role in this scenario: statues and paintings were exhibited in the parade (the so-called *tabulae pictae*, painted panels representing the highlights of military campaigns, together with the personifications of defeated populations and the artworks taken away from the enemy) together with real *tableaux vivants* composed by the prisoners wearing their national costumes (Fig. 1c) or by the triumphator driving the *quadriga* (chariot) wearing the characteristic triumphal clothing, especially the *toga picta* (Fig. 1b–f).

The Roman triumph was also a subject for iconography. The parade was part of the standard repertoire of Roman public art, the ceremony could have been depicted in its entirety (cf. the processions illustrated in the "small friezes" of the Arches of Titus and Septimius Severus in Rome and the Arch of Trajan in Benevento (Fig. 1e)), or just some of the main monuments of the parade became subject of iconography (the two reliefs illustrating the exhibit of the war chest (Fig. 1d) and the *quadriga* of Titus (Fig. 1a) located in the *fornices* of the Arch of Titus provide a good synthesis of Jewish triumph in 71 CE). Besides, the triumphator could have been depicted wearing his triumphal costume (cf. the statues of the *triumphali ornatu* and the use of the triumphal crown) and the *tabulae pictae* could have been transformed into monuments.

The historical reliefs depicting the Parthian war of 198 CE on the Arch of Septimius Severus are probably the marble copy of the paintings sent to the senate by the emperor together with the written reports of the military campaign (Herodian *Ab Excessu Divi Marci* 3.9.12). The transposition of these images on the triumphal arches erected along the very same itinerary followed by the ceremony increased the sense of correspondence between reality and representation, highlighting also the themes of eternality and universality of Rome's victory. The iconography of the Roman triumph exploited the qualities of images to communicate a message and the relationship between reproduction of a specific and unique ceremony and the symbolic meaning of its never-ending repetition in the many triumphs celebrated in Rome for centuries.

Costumes and Statuesque Types in Portraiture

Another key ceremony that helps to understand the connection between reality and representation in the Roman world is the funerals of nobles; they had an important role in the transmission of gentilician memory since the Republican period. As has been reported by ancient historians (Polybius *Historiae* 6.53.6-8; Diodorus Siculus *Bibliotheca Historica* 31.25.2), during funeral processions, actors represented the deceased's ancestors, wearing costumes (*habitus*) that recalled the public role of the ancestors at the peak of their political career while also wearing a mask depicting their features. In Roman society, in fact, social, political, public, and private status were expressed through clothing; accordingly, matters related to costume were often at the center of public debate as shown by the identity meaning attributed to the toga in opposition to the Greek cloak/*pallium* (Cadario 2010).

Iconography in the Roman World, Fig. 1 The iconography of triumph. (**a**) Titus on triumphal quadriga (relief, Rome, Arcus of Titus). (**b**) Octavian on triumphal quadriga (Denarius struck by Octavian). (**c**) Triumphal procession with prisoners (relief, Rome, Museo Nazionale Romano). (**d**) Triumphal procession with spoils (relief, Rome, Arcus of Titus). (**e**) Trajan on triumphal quadriga ("small" frieze, Benevento, Arcus of Trajan). (**f**) Marcus Aurelius on triumphal quadriga (relief, Rome, Musei Capitolini)

The creation in portraiture of a language related to the bodies of statues comes from the close relationship between costume and social identity/*status* and from the relation between choice of the statuary type and the motivations behind the dedication of a statue (Fejfer 2008; Cadario 2011). This language was based on the functional distinction between the statue's face that had to depict features and character of the person and its body that had to give more "objective" information about public role, career, and deeds. This language of bodies was codified between the end of the Republic and the beginning of the principate. It was based on a conventional repertoire of statuary types; often of Greek origin, it was changed in its format, costume (*habitus*), posture, gestures and "attributes" (*insignia*), and objects held by the subject (patera, scroll, lituus, wand, globe, lightning, weapons) or used as support located at the side or underneath a foot (armor, shield, *rostrum*, barbarian prisoner). Colors could also give important information; for example, they could help in distinguishing various kinds of toga while the choice of the statuary kind was done taking also into account the location, an essential part of the symbolic evaluation of the statue's dedication.

The diffusion of imperial statues and their frequent reunions displaying cycles of various members of a dynasty in power led to a clearer standardization of the bodies' language and an increasing internal diversification of repertoire to be able to express through the statuary types the internal hierarchies among the honored as much as their specific merits and public roles. The buyers were taking into account the reciprocal hierarchy and the meaning of each statuary type when they had to establish the modalities to honor the person.

The formats of Roman portraits, recalled also by Pliny the Elder (*HN* 34.18-20) in hierarchical order, included statues on cart (*quadriga* or *biga*) and equestrian statues (Fig. 2a), in sitting position (Fig. 2g) and standing. To these full-figured images we have to add the so-called abbreviate (*imagines clipeatae* (Fig. 2i), busts, herm) formats; in this case, more importance was given to the face, and the size of these statues offered the advantages of handiness and cheapness and they were mainly used in private funerals. For what concerns male costumes in portraits, at least in the western part of the empire, they were toga, armor, and nudity, respectively, symbolic of civilian, military, and "heroic" conditions. Other costumes, such as the *pallium* (the Greek cloak), were excluded from the public image in Rome, but not in the Greek cities, where they continued to illustrate the condition of good citizen; others, such as statues with Lupercus's or hunting clothes were much more rare. On the other hand, when it comes to female portraits, statuary types gave little importance to the realism of the costume (with a few exceptions: vestal portraits and those where the subject was wearing a *stola*); they rather prefer to take inspiration from the repertoire of Greek sculpture masterpieces to emphasize qualities (fertility or beauty) or virtues (chastity) and sometimes to give to the subject the appearance of a goddess.

Toga was the Roman civilian robe by excellence at least at official ceremonies, it was symbol of citizenship, complex distinctions of rank, class, and age (children wore an amulet around the neck (*bulla*), while triumphal statues wore the *toga picta*, identifiable by the colors). Accordingly, the statue with a toga was the most diffused and appreciated at all social levels; it was adopted by both *élites* to indicate their career and "provincials" to show their new status of freeing or citizenship. The costume changed over the centuries; its drapery evolved depending on fashion, political, social, and cultural reasons (Fig. 2b, c).

The cuirassed and naked statues, both borrowed from the Hellenistic world, if compared to the ones with togas, gave less specific information about the rank and career of the subject honored, but they assigned him warrior charisma and a superhuman aura. The cuirassed statue (Fig. 2d), born as a royal costume, was mainly used to highlight duties and military merits, its main public use was progressively limited to emperors and imperial family members. This statuary type also

offered the advantage of using the armor's surface for decorations illustrating typical topics of military propaganda; in this way, the cuirassed statue became a very efficient figurative *medium* such as in the breastplate of Augustus' statue from Prima Porta; the restitution of Crassus' legionary standards to the Roman people (20 BCE) has been placed in a cosmologic contest coherent with the beginning of the new golden age granted by the Augustan peace (Fig. 2h).

Nudity has been considered a costume that did not belong to the Roman tradition until the second century BCE when the prejudice against athletic nudity was overcome. After this, weapons were exhibited to add military charisma to the representation. The message, in naked or semi-naked portraits, was symbolized by the objects carried by the subject or used as a support and by the drape of the cloak; the drape could suggest heroic or divine characteristics. Statues with the cloak worn around

Iconography in the Roman World, Fig. 2 Language of bodies in Roman portrait. (**a**) Equestrian statue of M. Nonius Balbus from Herculaneum (Napoli, Museo Archeologico). (**b**) Republican togate statue, the so-called Arringatore (Florence, Museo Archeologico). (**c**) Togate statue of Augustus from Via Labicana (Rome, Museo Nazionale Romano). (**d**) Cuirassed statue of Drusus Maior from Caere (Rome, Musei Vaticani). (**e**) Hip-mantle nude statue of Divus Claudius (Ancient Olympia Museum). (**f**) Nude statue of Gaius Caesar (Ancient Corinth Museum). (**g**) Seated togate statue (Rome, Museo Nazionale Romano). (**h**) Breastplate of Augustus' cuirassed statue from Prima Porta (Rome, Musei Vaticani). (**i**) Imago clipeata with a togate bust from Cuma (Museo Archeologico dei Campi Flegrei)

the hips (*Hüftmantel*) (Fig. 2e) were more prestigious if compared to those that were completely naked (Fig. 2f). These considerations over the meaning of the costumes chosen are valid for statues as well as for images with the toga, *lorica*, or nudity included in reliefs, coins, or paintings.

"Roman" Iconographies: Public Ceremonies, Ludi, and Scenes of Work

The tendency to create a repertoire common to the entire empire is also present in another important aspect of Roman art (Elsner 1998: 27–51). The representation of significant historical events and the reproduction of main ceremonies and institutions typical of the public life constitute a key component of Roman art and iconography (Alfoldi 1999; Holliday 2002). A single historical event could have been represented to amplify, through its replica, its meaning in the political competition. When the Numidian king Bocchus delivered Jugurtha to Sulla in 105 BCE, he had the scene engraved on the ring that he then used as a seal; in 91 BCE, Bocchus represented the event with a statuary group, the *monumenta Bocchi*, erected in the *area Capitolina*; Marius tried to destroy it, while Sulla restored it (82–80 BCE). Finally, Faustus, Sulla's son, reproduced again the handover of Jugurtha on a coin minted in 56 BCE (*RRC* 426) (Fig. 3), probably copying the image originally created for the signet ring. The same iconography was replicated through different *media*, in both private and public contexts, in two or three dimensions, for almost 50 years covering an important role of propaganda during the first half of the first century BCE.

Iconography in the Roman World, Fig. 3 Denarius struck by Faustus Cornelius Sulla

The ceremonial and military functions of the state usually celebrated the commitment of the emperor, the army, and that of the most important state magistrates, all the while carrying a propagandistic content. The language used was cultured due to the level of the clients. The most frequently attested iconographies (scenes of triumph, battle, clemency and barbarian subjection, speech to troops (*adlocutio*), return and departure for the war (*adventus et profectio*), sacrifice, civilian oration, food distribution, apotheosis, etc.) were represented through various figurative media and realized at various scales according to the space available. Coins in particular provide an excellent source of information since they reproduce on a small scale a basic version of the same iconographies of the official historical reliefs together with legends that nowadays can be almost used as captions of the reliefs, too. So the legend *decursio* on a Neronian *sestertius* representing a single galloping horseman(*RIC*[1] 145) explains also the two horsemen "carousel" scenes located on the panels at the base of the Column of Marcus Aurelius, next to the apotheosis of Antoninus Pius and Faustina Maior: these two reliefs represent only a more elaborate version of the same subject.

A ceremony could have also been represented in a symbolic way, for instance, reproducing just the objects used during the ceremony and/or one or more categories of the participants. The iconographical scene of the sacrifice is a good example of this (Ryberg 1955). The various phases of the Roman ritual had been carefully selected to attribute to each one of them a direct or indirect easily recognizable iconography (Huet et al. 2004). The images of the procession of victims (Fig. 8) and musicians recalled the preliminary rituals (*praefatio*); libation was illustrated by the figure of the officiant of the ceremony pouring the contents of the *patera* over the altar; the killing (*immolatio*) and examination of the victim's viscera were represented by the *victimarius* depicted in the act of striking the figure of the already dead

animal; only the final banquet was not represented. Usually more actions, consecutive during the ritual, were represented in the same scene as shown by the Altar of the *Qurtii* from Angera (Fig. 4): libation was located at the center to highlight the figure of the ceremony's officiant or sponsor; the figures of some of the assistants, such as the flautist and one of the sacrificial victims, were used to refer to the previous and successive scenes of the ceremony (*praefatio et immolatio*).

Other iconographies were part of this official repertoire, they did not describe specific ceremonies, and consequently, they could be used in various scenes to introduce a reminder of the Roman ideology of victory. Those are images of trophies, often accompanied by winged victories, and prisoners of war. Images of prisoners, wearing different ethnic costumes to distinguish eastern and northern barbarians and depicted at the moment of defeat or clemency, and finally the images related to the personification of subdued populations and provinces were useful to mark the geographical extent of the empire.

Iconography in the Roman World, Fig. 4 "Ara" of the Qurtii from Angera (Milan, Museo Archeologico)

Other images, usually excluded from official art, show salient moments of civilian life. The people who promoted the games (*editores*) were often those who started this iconographic tradition with the intention to immortalize their generosity (*liberalitas*). The procedure was similar to the state's ceremonial but simplified; an iconographic *koiné* was created for each *ludus*, and it was realized through various figurative media and constituted by the representation of the show by a selection of its most relevant moments: *munera gladiatoria* were represented by the duels between gladiators, with different contexts and participants according to the specialty (Fig. 5a). In the *venationes* (scenes of hunting), the moment of the fight against the animal was depicted (Fig. 5a); circus games were represented by the initial processions and racing *quadriga*, and the background was often the one of the architectonic and sacred landscape of the Circus Maximus in Rome (Fig. 5b). The athletic games were summarized in the sequence of the three most violent matches: boxing, *pankration*, and wrestling; these events reminded viewers of the earlier Greek iconographic tradition (Fig. 5c).

Finally, we have to recall the "public" repertoire of iconographies related to the lives of common people, often depicted with a more simple and "popular" language (Clarke 2003). The representation of people in funeral contexts was in fact not just the privilege of the elite, as demonstrated by the discussion of the tomb of the literary character Trimalchio, who was a freedman (Petronius *Satyricon*, 71.5-8). The representation of various scenes of work depicted the person who died performing actions related to his or her profession (*res gestae*) (Zimmer 1982); these iconographies provide us with information about daily life in the Roman world. The biographical sequences depicted on sarcophagi were similar, as they represented the life of the deceased through a selection of meaningful episodes: scenes of the daily life of women or children, comedic scenes, and convivial scenes that updated the Greek iconography of the symposium through the

Iconography in the Roman World, Fig. 5 The iconography of the ludi. (**a**) Amphiteatral games: munus gladiatorum and venatio (funerary relief from Pompeii). (**b**) Circus games (picture from a mosaic in Luni). (**c**) Athletic games (sarcophagus, Rome, Museo Gregoriano Profano). (**d**) Damnatio ad bestias (mosaic from El Djem, Thysdrus)

introduction of new contexts, the *triclinium* first and the *stibadium* afterward (Dunbabin 2003).

The creation of these new images often happened through a process of transformation (or Romanization) of Greek models and figurative types, adapted to the new contents and sociopolitical context by including appropriate details. The iconography of hunting in the Hellenistic period was usually reserved for the image of the king, mostly in Macedonian contexts (e.g., Alexander the Great) to illustrate the courage (*areté*) that justified his role. This aspect is present in Rome in rare images of aristocrats or emperors hunting, such as the eight circular reliefs (roundels) of the Hadrianic period that decorate the Arch of Constantine. In the iconography of *venationes*, the Hellenistic tradition had been deeply transformed by the new context of the amphitheater;

Iconography in the Roman World, Fig. 6 Capture of beasts (mosaic from Piazza Armerina's Roman villa)

extraordinary creativity was displayed by the variety of prey hunted by the *venatores* (cf. the mosaics of the Zliten villa (Libya) or the relief from Obzor (Thrace), today in Sofia, Bulgaria) and the cruelty of death sentences executed by beasts (*damnatio ad bestias*) (Fig. 5d).

Another activity apparently marginal as the capture and transportation of exotic beasts has been the object of a complex and detailed representation attested by some of the mosaics of the Imperial Roman villa in Piazza Armerina, Sicily (Fig. 6). The repertoire of the iconography of hunting in the Roman world was very complex and efficient in its illustration of hunting roles in society at that time.

"Greek" Iconographies: Divinities and Images of Myth

A substantial portion of the images of the Roman repertoire derived from Greek models; in this way, the Classical world often shows a millenary iconographic continuity. The transmission of this heritage to Rome started during the Archaic period, facilitated in part by Etruscan influence, and continued during the Late Republic, when Rome itself gradually became one of the main artistic centers of the Hellenistic world (Pollitt 1978). The authority attributed to the Greek culture influenced the iconography of the Roman pantheon (from cult statues to votive images) and the main cults (such as the Dionysiac cult) and myths; these images of Greek origin were often used in new contexts, thereby gaining new meaning. For instance, the many Roman copies of Greek masterpieces, used as statuary ornaments in villas and *domus*, are examples of statues that were meant to be displayed in temples, sanctuaries, theaters, and agorai, but often ended up in private spaces. The athletes' images were used in many villas to reproduce Greek gymnasia on a small scale; for example, in the peristyle of the Villa of the Papyri in Herculaneum, the two statues representing runners at the start of a race, copies of an original dated between the end of the fourth century BCE and the beginning of the third century BCE, were meant to recreate the atmosphere of a competition in the space between the arcade and the big *natatio* (Romano and Warden 1994). The original meaning was consequently changed by the new context.

For what concerns mythological scenes, their repertoire, originally from Greece, was increased by the new iconographies in the Roman world (e.g., images of Roman myths such as the nursing of Romulus and Remus or the romance of Dido

and Aeneas). These images related to myths were also modified by the new context of use and progressively became "cultural icons" (Zanker 2002). Their symbolic meaning was connected with the person who commissioned them to decorate the walls of his residence or to the deceased who chose them for his funeral monument. Their naturalism could attract the observer and induce him to believe to be living in the imaginary world of the Greek myth, or it could recall a series of intellectual connections to understand a decorative plan usually based on the combination of different myths. This phenomenon was related to painting and sculpture and it led to new iconographies related to the reinterpretation, often sophisticated, of Greek myths (such as the eight reliefs of the Palazzo Spada (Fig. 7), executed for a villa in the second century CE (Newby 2002)).

The most interesting result of this recontextualization was the new biographical cycles of gods and heroes, such as the one imagined by Longus (*Erotica* 4.3.2) in a temple of Dionysus in Mytilene (on the island of Lesbos) depicting the god in a series of consecutive scenes. The combination of the creation of a visual language and its inclusion into a narrative dimension is an important development introduced by the Romans in the iconography of mythology. In the exemplary case of Achilles, the existing images of various episodes of his life, often of Classical or Hellenistic origin and represented through different figurative meanings in the

Iconography in the Roman World, Fig. 7 The reliefs from Palazzo Spada (Rome, Palazzo Spada). (**a**) Bellerophon and Pegasus. (**b**) Amphion and Hermes (?). (**c**) Paris and Eros. (**d**) Paris and Oenone. (**e**) Diomedes and Odysseus. (**f**) Pasiphae and Daedalus. (**g**) Death of Opheltes. (**h**) Dying Adonis (?)

Imperial period, were little by little reunited into a very articulated biographic cycle (birth, *paideia* with Chiron, life at Scyrus, and the Trojan War) in Late Antiquity. New scenes were introduced to fill the voids in the figurative reconstruction of the hero's life. This repertoire had been replicated with different typologies of objects (Ghedini 2009). The figurative cycle of Mithras was new in its contents and iconographies; it described the deeds of the god next to the big tauroctony scenes.

Images of Context

As has been observed, Roman iconography provided a variety of subjects that helped construct important relationships between images and memories, as well as events both actual and mythical; these iconographies serve to guarantee the messages and provide other meaningful characteristics. The standardization of this repertoire is a general phenomenon that concerns state-level ceremonies, the images of games (*ludi*), and mythological scenes as well as a general tendency to include these images in brief cycles, usually composed of a series of scenes separated one from the other. The iconography was in fact also influenced by the patterns of narration in which it was included since they could modify the scheme (Brilliant 1984). A long continuous frieze, such as the exceptional one depicted on the Column of Trajan, had a size that made the difference in the representation if compared to the narration through separate scenes/panels or to single reliefs; on the other hand, the space available in sarcophagi was often a composition of sequences where various scenes were arranged into a hierarchical order.

The introduction into different narrative forms could change, even deeply, the iconography: the *suovetaurilia* (Vermarseren 1957) was a Roman ritual of purification; its distinctive element was the presentation of the three sacrificial victims (pig, ram, and bull). They usually are presented in a sequence, as in the Altar of Domitius Ahenobarbus (Fig. 8a) (the order is reversed in this case) or as in a relief of the base of the Decennaliain the Louvre in Paris (Fig. 8b) (with the three victims in the "correct" order). On the Column of Trajan, the *suovetaurilia* is represented through three different scenes, each one placed at the beginning of one of the years of the Dacian war; if we look at all of them at the same time, we see the progressive advancement of a procession around the *castra* (Fig. 8d–f). The Trajanic frieze, using a bird's-eye view, could show the itinerary of the procession and recall that the ritual had the aim of purifying the participants within it. The limited space of the panel of one of the Aurelian reliefs reused on the Arch of Constantine led to a different composition again; the three animals are almost overcome by the procession, depicted illusionistically as if they are advancing from the back of the relief ground (Fig. 8c). The same iconography has led to interpretation and compositions each very different one to each other due to the narrative form. These solutions gave different information to the spectator: for instance, the emphasis of the itinerary of the procession around the *castra* of the Column of Trajan clarified that the ritual of purification, conducted by the emperor, concerned the military.

Finally, we have to mention the importance of where the images were located; their location was regulated with the aim to achieve a correspondence with the buildings and the rest of the decorative plan. Vitruvius (*Arch*. 7.5.6) promoted the relationship between the statuary type and the functions (*proprietates*) of their location. The location in a public or private context could influence even deeply the iconography: for instance, the increasing violence in scenes depicting *venationes* and *munera gladiatoria* between the second and the fourth centuries CE and their location in high-class villas and houses. These were private spaces designed for pleasure (*otium*) that evidently was nourished also by the memory of the bloodshed during the *ludi*; the kind of space where the images were located led to the major cruelty visible in the images (Papini 2004).

Future Directions

It is possible to fully understand the meaning of an image only if the image exists within a context (Rose 2010); the context is not just the physical

context of use (buildings or objects) but also the social and cultural context where the image was created and produced. If images do not have a dialogue with what surrounds them, they are mute: we must consider the iconographic tradition of their context, the formal language chosen for their representation, their relationship with the literary tradition, the function of the figurative media adopted, the material context in which they were produced and circulated, the kind of clients and public that will enjoy them, taking into account a different perception of the images according to the social class and cultural competence of the viewer.

Iconography, Etruscan

L. Bouke van der Meer
Classical Archaeology, Faculty of Archaeology, University of Leiden, Leiden, The Netherlands

Introduction

The Etruscan culture lasted from c. 1000 to c. 30 BCE. The prehistoric and protohistoric period, also known as the Proto-Villanovan (final Bronze Age) and Villanovan culture (Iron Age), lasted from c. 1000 until c. 700 BCE and the historical period from c. 700 BCE until the reign of the Roman emperor Augustus (r. 31 BCE–CE 14). The artistic and artisanal output of the Etruscans, who lived mainly in *Etruria*, the area between the Arno and Tiber rivers, in the Po valley and in parts of Campania, is enormous. Vases, wall paintings in tombs and temples, stone reliefs, bronzes, terracottas, sarcophagi, funerary urns, and pieces of minor art (engraved mirrors, appliqués, gems, scarabs, ring stones, *bullae*, molds, stamps, coins) yield thousands of figurative scenes from the quotidian, magisterial, funerary, and mythological domains. They raise many questions. Were they intended as merely decorative or as meaningful? Did they have only one meaning or were they polysemantic? What is the origin of the mythical scenes? How and why were they chosen? Which non-Greek, typically Etruscan iconographic phenomena can be detected? Until the 1970s, some scholars presumed that the Etruscans did not understand and therefore banalized Greek myths. Recent research, however, makes clear that though some scenes may show evidence of misunderstandings or conflations (see below), most others make sense and frequently harbor a moralistic, ideological, propagandistic, or possibly political meaning (Krauskopf 1974; Massa-Pairault 1992; Menichetti 1994; Massa-Pairault 1999; van der Meer 2004).

Definition

Iconography is not taken as image, portrait, statue, or the description and interpretation of images here but rather as iconology. The latter term means the study of images on all levels, in widening circles, that is in relation to the image bearers (monuments or artifacts), their micro-context (in the case of a poly-scenic iconographical program), function and macro-context (city or settlement, sanctuary, necropolis, tomb), and period, society, group, patron, and artist (style). Most images are the products of elite and middle class society, while few can be related to the lower classes. Changes in society and politics are often reflected by art and image, although some themes like those of the banquet and symposium attest to tradition and homeostasis in elite contexts, from prehistory to the first century BCE.

Historical Background

The oldest figurative scenes on artifacts of the prehistoric period can be dated after c. 800 BCE. They are rendered in a local geometrical style, mostly on biconical funerary urns, in weapons, and in the minor arts, showing symmetrical scenes of leave-taking or meeting (shaking hands), hunting, ritual dances, and weaving, often gender-related. The hunting of a boar by a lone man may be an example of self-representation and heroization. Human figures are rendered in profile or in frontal view. Contacts with the Greek Euboean colonies Kumai and Pithekoussai in Campania after c. 750 BCE led to the introduction

of the Greek geometric style, resulting in the appearance of mythological scenes of Greek origin during the Orientalizing period (c. 700–600 BCE). Sources of inspiration for these scenes included imported ceramics, itinerant Phoenician and Greek artists, and oral tradition. The immigrant Euboean potter Aristonothos depicted a Greek myth (Odysseus and Polyphemos) on one side of a vase but an Etruscan sea battle on the other side, thereby conforming to the wishes of his Italic patron. In the following Archaic period (c. 600–480 BCE), Etruscan gods, some with names of Italic origin like Menerva, were rendered for the first time in anthropomorphic fashion as statues or images, primarily due to the adoption of representations seen on imported Corinthian, Attic, and other Greek vases. The fifth century BCE was a period of crisis, especially along the Tyrrhenian coast, whereas the fourth century heralded a kind of artistic rebirth, with strong influences from Greek southern Italy, especially Apulia. The gradual reduction of the Etruscan states by Rome, between 396 and 240 BCE, did not result in immediate Romanization and Latinization. The importation of artists from Greek areas to Rome and Etruria in the Hellenistic period (c. 330–30 BCE) caused the introduction of successive, stylistic, and compositional models from Tarentum, Pergamon, Rhodes, Athens, and Rome itself. Distinct Etruscan art and imagery disappeared around 30 BCE, around the time when Latin replaced the Etruscan language. Although Etruscan iconography is heavily indebted to Greek art, countless scenes show a process of adaptation, reinterpretation, and original creativity.

Key Issues

Etruscan images, both originals and those (often partly) copied directly or indirectly from Greek archetypes and transmitting models, exhibit interesting characteristic phenomena which are presented in the following overview. The phenomena, some of which partly overlap, follow an internal chronological order.

Self-Representation and Identification

As stated above, self-representation is already visible in prehistoric artifacts. In the seventh century BCE, non-mythical scenes portray quotidian activities and funerary rituals. Some of them evidently have more than one meaning. A famous Etrusco-Corinthian jug dated to c. 620 BCE from a grave at Tragliatella, a settlement near Cerveteri, depicts the meeting between an Etruscan warrior and his wife (*Ammarce* (which should perhaps be read as *Mamarce*) and *Thesathei*), a cavalry engagement of two men in a labyrinth (*truia*), two couples making love, seven identically armed marching or dancing warriors, and the abduction of a woman overseas (*ThesCRA* I, s.-v. Processions, Etr. 34; van der Meer 1986: 169, Fig. 1). There is consensus now that some scenes of the narrative are influenced by the adventures of Theseus and Ariadne. This implies that the deceased wished to present themselves as heroic aristocrats. The *truia* vase shows that the iconographic program is the result of a creative, eclectic process.

Since several other scenes of Greek origin (e.g., Odysseus, the Argonauts) occur on Etruscan vases and on an ivory *pyxis* (round toilet box) from Pania near Chiusi, the choice of Greek myths may also have been influenced by the fascination for heroes traveling overseas, which is understandable since the Etruscans were first-class seamen and pirates.

The need for comparison and identification is present in later centuries too. The painted program of the François Tomb at Vulci, dated to c. 340–310 BCE (Massa-Pairault 1992: 119, Figs. 104–108), shows that the deceased Vel Saties and his companion compared themselves to or identified themselves with Greek heroes, namely, the wise Nestor and his friend, Phoinix. Symmetrical scenes showing men from Vulci slaughtering a king of Rome, thus representing sixth-century BCE history on one wall, and Achilles slaughtering Trojan prisoners on the opposite wall suggest that men from Vulci in the past and present are intended to be compared to successful Greeks on the one hand and the defeated Trojans with the Romans *cum suis* on

the other hand. The *heroon* of Aeneas at Lavinium (Latium), dated to c. 330 BCE, proves that the Romans connected their own origins with the city of Troy. Apart from reproducing the glorious past, the visual program of the François Tomb betrays wishful thinking, understandable in light of Rome's threatened conquest of Vulci. Identification is also seen in the names of supposed founders of Etruscan cities, who are always Greeks. This creation of roots probably originated in the fourth century BCE. Elite families also chose their own Greek hero. Laris Pulenas, a *haruspex* (seer) represented as a male figure on the lid of a Tarquinian sarcophagus dated to c. 250 BCE, presents the famous Greek seer Polles, called *Pule* in Etruscan, as his ancestor in his funerary inscription, something akin to a modern resumé. Daidalos (Etr. *Taitale*; *Taitle*), the famous inventor, served as a popular example for artisans and craftsmen. His images are common on artifacts from the seventh to the first century BCE (van der Meer 1977/8: 65; 108–109, Figs. 30–33). They testify to a *longue durée* identification, which persists until Late Antiquity.

Identification or association is also shown in incised images that appear on mirrors, like one from Perugia showing *Lasa Achununa* (Lasa (the) "Achu-nian") and *Atunis* (Adonis), which was found in the necropolis of a family called *Achu*. *Lasa*, assistant of *Turan* (Aphrodite), is a good example of another frequent phenomenon on mirrors: substitution (van der Meer 1995: 195, Fig. 93). The famous Bronze Liver of Piacenza, dated to c. 100 BCE, shows a similar replacement. In the inscribed pantheon, Lasa is mentioned but Turan is absent (Maggiani 1982 [1984]: 55–57, Fig. 1). The question of whether archaic terracotta statue groups (Massa-Pairault 1992: 61–62, Fig. 43) and reliefs of temples in Rome and Latium representing Herakles and an armed goddess (Athena?) attest to an identification wished by a king (such as that of the tyrant Peisistratos in Athens) has not yet been satisfactorily answered (Lulof 2000). More personal objects like fifth-century BCE scarabs show a plethora of Greek heroes with inscribed Etruscanized names, but Krauskopf's hypothesis that the bearers identified themselves with heroes is not convincing since men like Kapaneus were "bad guys" (Krauskopf 1999: 405–421).

Moralizing Images

One of the earliest examples of a moralistic narrative can be found in the painted program of the Tomb of the Bulls at Tarquinia, dated to c. 540 BCE (Brendel 1978: 167, Fig. 109). The frieze on the rear wall of the second room shows a heterosexual group in action and the erotic union of two homosexual men. In the first scene, a recumbent cow lies quietly, her back turned to the group; in the second, an aroused bull with a bearded man's face, which looks like the head of the libidinous Greek river god Acheloös, is about to attack the two men. So, evidently, at least in this funerary context, heterosexuality was seen as reproductive and homosexuality as non-fertile and therefore undesirable.

The roofs and pediments of Etruscan temples were decorated with terracotta statues or groups in the archaic and classical period, so-called *antepagmenta* (rectangular plaques in a pediment) and antefixes (vertical roof tile covers). A fascinating *antepagmentum* belonged to temple A at Pyrgi, the harbor city of Cerveteri (Brendel 1978: 234–235, Figs. 163–164). The temple, now dated to c. 470 BCE, was probably dedicated to the Aurora-like *Thesan*, whom ancient Greek writers assimilated with the Greek goddess Ino/Leukothea (Polyaenus, *Strategemata* 5.21). The tympanum plaque features the Seven against Thebes in overlapping groups. Zeus strikes one of them with his lightning bolt, and Athena withdraws the potion of immortality which was destined for one of the Seven, because of his cannibalistic behavior. The theme was probably chosen to show the *hybris* (recklessness; pride) of warriors and the punishment of bad behavior by the gods. Apart from the moralizing warning, the link with Thebes may have been important: Ino/Leukothea, goddess of light, was strongly worshipped in Thebes.

In the Hellenistic period, four scenes of the Theban Seven are also visible in the northern, completely filled pediment of the temple of *Tina* (Zeus) at Talamone, dated to c. 150 BCE (van der

Iconography, Etruscan, Fig. 1 Volterran urn showing Orestes and Pylades twice (Volterra, Museo Guarnacci, inv. 345; photo Dainelli, Volterra)

Meer 1977/8: 104, Fig. 19 (drawing); *LIMC* I,1 s. v. Amphiaraos 45 (photo)). Here too the tragic consequences of a battle between brothers is shown, obviously with a message: the bad men, Oedipus' sons, kill each other, and a good man, Amphiaraos, a seer, is saved by Zeus from death by letting him disappear into the earth. Oedipus' sons and Amphiaraos also appear in the paintings of the François Tomb mentioned before. In addition, the funerary urns from Chiusi, Volterra, and Perugia dated to the second and first centuries BCE, with schemes similar to those at Talamone, also frequently show Theban scenes. They may have been chosen because of the Etruscan fascination for chains of successive, fatal events. Steuernagel (1998) presumes that the urn images encouraged the elite to stick to the old aristocratic sacrificial rituals and values (cf. Stevens 2010: 77–110).

A terracotta *akroterion* from the top of the pediment of a small temple in the sanctuary in the Cannicella necropolis at Orvieto, dated to c. 480 BCE, shows Orestes killing his unfaithful mother Klytaimnestra, a theme which is also present on some bronze mirrors. In both contexts, we may assume that the images contain a warning against the consequence of adultery (Stopponi 1991: 1103–1161, Fig. 17; 25–27). On an alabaster urn from Volterra (c. 200 BCE; Fig. 1), the matricide is shown in two scenes, like Etruscan inscriptions which are read from right to left, Orestes (inscribed *Urste*) and Pylades (*Puluctre*) about to kill Klytaimnestra (*Clutmsta*) and her lover Aigisthos, and their kneeling on an altar, threatened from below by two Underworld demons, *Charun* (derived from the Greek Charon) wielding a hammer and *Vanth*, his female colleague, holding a torch. This sequence proves a rather good knowledge of successive episodes of one Greek tragedy. The type of altar and the Etruscan demons lend the scenes a local flavor. The asylum-seeking eventually brings about the salvation of the avengers (for possible literary or theatrical influences on urn reliefs, see below).

Some bronze mirror engravings may harbor a moral message, too. One dated to c. 450 BCE shows a standing, almighty *Turan* (Aphrodite) and a seated, boyish Alexandros (Paris) trying to seduce Helena, who is lying in bed with her baby Hermione (*LIMC* IV,1, s.v. Helena/Elina 5 (with figure)). The sphinx hovering over the scene foretells the disastrous consequence of adultery and abduction: the Trojan War.

Domestication

In many mythological scenes, the core is Greek with inserted or added figures of Etruscan origin.

Iconography, Etruscan, Fig. 2 Volterran urn depicting the assault on Thebes (Volterra, Museo Guarnacci, inv. 370; photo Dainelli, Volterra)

The addition and consequent hybridization mean that Greek myths were reinterpreted by Etruscan artists, in other words, the scenes received an Etruscan flavor (van der Meer 1995; de Grummond 2006). In scenes on mirrors showing the birth of *Menerva* (Athena) from the head of *Tina* (Zeus), the upper god is assisted by Etruscan goddesses like *Thanr* and *Thalna* in the role of midwives (*LIMC* II,1, s.v. Athena/Menerva 218 (with photo)). The embracing of *Tina*'s belly by *Thalna* as if he were giving birth like a sitting woman, an activity which does not appear in comparable Greek vase scenes, proves that the engraver inserted the local delivery practice, thereby showing that he had understood the myth. Many fourth- and third-century BCE mirror scenes of Greek origin show another frequent form of domestication, namely, the insertion of the façade of a house, palace, or temple into the background, a decor which is absent in comparable older or contemporaneous Greek representations (van der Meer 1995).

Hellenistic stone urns from Volterra and Perugia show a similar domestic element. The assault of the Seven takes place against a Thebes represented with an Etruscan city gate instead of a Greek one, thus situating the tragic attack in a local context (Fig. 2).

Actualization

Images are products of their time. A shift in the rendering of a theme is an indication of a changing custom. Etruscan banquet and symposium scenes initially show the participants sitting down (Tuck 1994), whereas after c. 580 BCE, they are reclining on wooden beds. The change is due to the imitation of the Greek custom, which became in vogue in the same period. The schemes may have been copied from depictions of *klinai* (dining couches) on imported Greek vases, among others, because young male assistants carrying wine to reclining couples are rendered nude, whereas in reality they were dressed (Diodorus Siculus, 5.40).

Even military events may have left traces on artifacts. It has been suggested that bronze mirrors dated to c. 470–450 BCE showing Eos with her dead son Memnon in her arms (*LIMC* III,1, s.v. Eos/Thesan 23–25 (with figure); cf. Brendel 1978: 287, Fig. 203) may reflect the loss of young soldiers during the fatal naval battle of the Etruscans and Greeks from Syracuse off Kumai in 474 BCE.

The theme of Achilles killing Trojans on Etruscan stone sarcophagi is often related to the cruel slaughtering of Roman soldiers by the Tarquinians in 356 BCE, described by Livy in his *Ab urbe condita* 7.15.9–10 (van der Meer 2004: 32–33).

In painted banquet/symposium scenes in archaic and classical period tombs at Tarquinia, women recline with their husbands, but at the end of the fourth century BCE, they are depicted sitting at their husbands' feet (Brendel 1978: 340, Fig. 265). This change may be due to Rome's conquest of Tarquinia. The Etruscan elite was probably forced to change a custom that was not considered acceptable in Roman society.

The effects of historical events are visible on Hellenistic urns too. Two urns of *marmo alabastrino*, still present in the Tomba della Pellegrina at Chiusi belonging to the *gens* Sentinate (c. 250–230), depict a battle between Celts and others, possibly a reminder of the fierce battle at Sentinum (in Umbria) between Celts, assisted by Umbrians and Etruscans, and Romans in 295 BCE. The Sentinate family may have originated from Sentinum, where their ancestors may have participated in the battle won by the Romans (Maggiani 1990: 207, Fig. 16; pl. 4, 4).

The enormous number of terracotta urns from Chiusi featuring the historical Athenian farmer Echetlos or an Etruscan farmer fighting with his plow against enemies is often assumed to reflect and symbolize the battle of farmers against the agrarian reforms of the Gracchi in the second century BCE (*LIMC* III,1 Echetlos 2; de Grummond 2006: 199, Fig. VII.28).

Symmetry

Symmetry is a frequent phenomenon from prehistory onward. It is found on Villanova ash urns showing two humans sitting opposite one another, right above the remaining handle. Similar compositions are found in archaic tomb paintings, e.g., mourners to the left and right of a fictive door to the Underworld (Brendel 1978: 169, Fig. 110); Castor and Pollux, both with a horse (e.g., Brendel 1978: 192, Fig. 127); and thematically related scenes (dance, procession, sport) on the long walls leading toward the eye-catching rear wall. The thematic symmetry in the François tomb has already been mentioned. Some bronze mirrors exhibit a similar phenomenon. The most instructive example is the famous *Athrpa* mirror, now in Berlin (Brendel 1978: 366, Fig. 284). In the center stands a winged woman labeled *Athrpa* (Atropos) holding a small hammer in her right hand. Above her the head of a boar is visible. On the left are *Turan* and *Atunis* (Aphrodite and Adonis); on the right is another couple, *Meliacr* and *Atlenta* (Meleagros and Atalanta). In ancient Greek literature, these couples are never mentioned together. The engraver combined them intentionally because the two men, Adonis and Meleagros, were killed in confrontations with boars. Atropos ("the Irreversible") is one of the three Greek *Moirai*, the goddesses of fate, who announce death. In Greek art, she uses scissors as one of three goddesses of fate but on the mirror a hammer, probably to pin the boar's head to an invisible wall. For *Athrpa*, the engraver used an exchangeable scheme; he copied her from Greek Nike, goddess of victory, as represented on silver coins from Syracuse, dated to c. 310 BCE. On these, Nike carries a hammer and is about to attach spoils to a *tropaion*, a bare trunk, which indicates the turning point in a battle. In a similar way, the Aphroditic goddess *Lasa* holding a scroll, a *liber fatalis*, stands between two Greek heroes on another mirror (van der Meer 1995: 222–227, Figs. 105–106; Harari 1995: 103–111).

Thematic symmetry is also present on several stone relief sarcophagi, dated to the end of the fourth century BCE. A sarcophagus from Torre San Severo near Orvieto – decorated on all four sides – for instance, shows Achilles killing Trojans on one long side and Achilles' son Neoptolemos killing the Trojan princess Polyxena on the other side, both in similar schemes. Not only do these scenes have a common theme, but they

also represent a chain of fatal events. The short sides show successive stories pertaining to Odysseus: his visit to Kirke and his sacrifice to the spirits of the deceased in order to gain information from the shade of the seer Tiresias as to how he could return to his home in Ithaka (van der Meer 2004: 29–39, Figs. 7–8, and 30). The latter sequence has a positive message: salvation. Rescue scenes are common on Hellenistic urns too, the most popular themes being the recognition of Paris and the sacrifice of Iphigeneia (see below).

Some symmetries seem to be gender-related. The famous sarcophagus with Amazonomachies painted on all four sides which belonged to an elite woman shows losing Amazons on two sides but victorious ones on their opposite sides (Brendel 1978: 342, Fig. 266, 384, and 296; *LIMC* I,1 Amazonae etruscae 29 (photo)). Amazon victories are absent from Greek visual art.

Symmetry is also common on sarcophagi and urns bearing a so-called heraldic scheme: a *patera* flanked by griffins or sea monsters. The wine cup may hint at the joys of the symposium which awaits those who travel to the Blessed Islands in the Underworld (van der Meer 2004: 111–118).

The most recent mirrors without inscriptions, found in third-century BCE male graves, very frequently show Castor and Pollux in a mirrored scheme, indicating a hero of mortality and one of immortality. The image probably represented the hopes of an eternal afterlife.

Conflation

Conflation may have been the consequence of the artist's amalgamation of elements from two myths or parts of two or more models. This happened when stories had a similar content or heroes played a similar role. The best example of this is an engraved scene on a now lost inscribed mirror (Fig. 3) featuring from left to right *Mine* (Minos), *Menrva* (Athena), *Vile* (Iolaos), *Ariatha* (Ariadna), *Hercle* (Herakles), and *Thevrumines* (the Bull (*thevru*; from Greek *tauros*) of Minos (*Mine*): Minotauros). In Greek myth and art, it is Theseus who kills the Minotaur. The engraver made the error because he also had vague knowledge of Herakles slaying a bull (van der Meer 1977/8: 85). Female names Ariadna and Klytaimnestra are transformed so that they end like Etruscan female first names do, on – *tha*/*ta*: *Aria-tha, Clutms-ta*. The transition from *Clutum-* to *Clutm-*, evidence of the syncopation that took place after c. 460 BCE, is a strong indication that the owners of mirrors, usually women, liked to converse about myths.

Iconography, Etruscan, Fig. 3 Drawing of a lost bronze mirror showing Herakles and the Minotaur (from *BABESCH* 52–53, 1977–78, 129, Fig. 100)

The Transmission of Themes and Schemes

Etruscan images are mono- or poly-scenic. Polyscenic scenes, like Odysseus's escape from Polyphemos' cave and his getting past the dangerous Skylla, a barking sea monster, on the ivory *pyxis* mentioned before (Krauskopf 1974: pl. 2–3), are quite exceptional because the combination of two successive, narrative scenes has no parallel in contemporaneous Greek visual art. While the escape scene occurs on Greek vases, the Skylla scene is absent. This may imply that the ivory carver also had oral information about the myth, ultimately based on Homer's *Odyssey*, and thus created his own little narrative, cyclic representation.

Places where Etruscan and Greeks met frequently were in the first place sanctuaries near

the harbors of Tarquinia and Cerveteri. Myths and rituals, e.g., of Adonis, were introduced by Greek merchants from Ionia, the Greek islands, and Athens but reinterpreted by the Etruscans. Although there was a language barrier, they must have talked about myths. The frequent Atunis (Adonis) scenes on fourth-century BCE mirrors have elements in common with images on two gilded, red-figure *hydriai* of the Athenian Meidias Painter dated to c. 410 BCE featuring the beautiful heroes Adonios and Phaon, vases which were found in the tomb of a priestess of Turan (Aphrodite) at Populonia: the presence of musical instruments, a magic bird (a wryneck; *iynx*) and a *rhombos* (magical turning wheel). Comparison shows that the mirror engravers added non-Greek elements like an *alabastron* (perfume vase) and a spatula, objects not present on the Meidias vases but which obviously belonged to the Etruscan *mundus muliebris* (Brendel 1978: 364, Fig. 364). The comparison does not mean that engravers saw Meidias's vases but Meidias's motifs may have been transmitted by memory, textiles, or other image carriers.

The phenomenon of presenting successive scenes from a single myth also occurs on so-called stone hall sarcophagi from the fourth and third century and urns from the second and first century BCE, particularly those depicting Trojan and Theban stories (Brendel 1978: 385, Fig. 297). There are some indications that papyri illustrated with successive epic scenes were used. An alabaster urn from Volterra bears two successive scenes from the *Iliad* books 3 and 4 that are also visible on a marble plaque (the so-called *Tabula Iliaca Capitolina*) which illustrates the main scenes of the 24 books of the epic in small panels furnished with Greek texts (Squire 2011). The *Tabula* dates to the period of Augustus. Since the makers of the urn and the *Tabula* cannot have seen each other's work, a common source must be postulated. The back of the *Tabula* bears an acrostic which is similar to that of Eudoxos in an illustrated, astronomical papyrus, dated to c. 165 BCE. This coincidence suggests that a multi-scene papyrus or another, similar image carrier functioned as a model for both the maker of the urn and the maker of the *Tabula* (van der Meer 1977/8: 77–78; 120, Figs. 72–75; for cyclic scenes, see also Maggiani 2000: 9–18).

Many urns from Volterra and Perugia depict themes which are present in Roman tragedies of the second century BCE, especially those of Ennius, who used tragedies of Euripides but added realistic Roman elements. On many urns from Perugia showing the Sacrifice of Iphigeneia, one of the soldiers, probably Achilles, is about to cast a stone, a detail present in Ennius' *Iphigenia* but not in Euripides' tragedy (van der Meer 1991: 119–136, Fig. 1, pl. 36). It seems likely that Etruscans performed tragedies based on Roman versions, since the stone theater in an extra-urban hill sanctuary in Castelsecco, near Arezzo, dates from c. 150 BCE, a period when the Etruscan language had not yet been replaced by Latin. In addition, stone theater-like tribunes in front of tombs, and many terracotta masks found in tombs, suggest that theater plays were not only performed in sanctuaries but also in necropoleis.

Current Debates

Elucidating the semantic content(s) of images is a fascinating research challenge. More theoretical and methodical reflection is needed in order to avoid the danger of overinterpretation (Spivey 1994: 213–215; as for theory, see Junker 2005: 108–118). The introduction of an "internal combinatory" method by de Grummond (2006: 15–18), implying the comparison of series of similar Etruscan images, is a step forward, but it should not be applied without paying attention to possible Greek sources. The current debate is focused on the possibly polysemous character of many images, especially those that have been borrowed from Greek sources. Another aspect concerns the way schemes and themes were transmitted: by itinerant artists, imported artifacts, visual models (textiles, papyri, parchments, and molds), memory, and oral information and possibly by literary sources, tragedies, or even performed stage plays.

International Perspectives

For further iconological research, it is a conditio sine qua non that the *Corpus Speculorum Etruscorum (CSE)* and the *Corpus delle urne etrusche di età ellenistica (CUE)* should be completed. Modern research like microscopic analysis, the use of databases, statistics, and the study of the metal composition of artifacts, e.g., of mirrors (see Wiman 1990), will add information on artistic centers, workshops, engravers, and their modus operandi. In addition, more collaboration between experts of different disciplines, especially the exact sciences, languages, epigraphy, art history, and the archaeologies of Egypt and the Near East, is needed.

Ideology and Materiality in Archaeological Theory

Paul R. Mullins[1] and Courtney Singleton[2]
[1]Department of Anthropology, Indiana University-Purdue University Indianapolis, Indianapolis, IN, USA
[2]Department of Anthropology, Columbia University, New York, NY, USA

Introduction

The notion of ideology has been wielded by a vast range of archaeologists studying every conceivable period and subject, and it has been defined in an equally vast range of forms. In various hands, ideology looms as instrumental misrepresentations of objective reality, a structured body of ideas imposed on a group of people, or a general worldview shared by a society. It is not necessary or even desirable to develop a single definition of ideology, but many analyses of ideology risk reducing it simply to generalized ideas and practices, and others detach it from any concrete power relationships. This entry focuses on scholarship that defines ideology as a body of representations that mystifies and masks concrete power relationships, typically to promote the interests of a particular social collective. This approach situates ideology squarely within relations of inequality, assuming that dominant representations of reality rationalize, disguise, and distort lived inequalities, and it focuses on how archaeologists can examine the ways goods and material discourses are defined and contested as ideological mechanisms. The interests of dominant collectives are opposed in modest and consequential ways to the interests of other social collectives, and ideology always is embedded in (and attempting to rationalize and reproduce) those power inequalities. Certainly nothing could be more material than such power, so archaeological scholarship on ideology has powerful potential to examine how goods are implicated in systems of inequality, variously reproducing them, negotiating inequality, or being wielded against dominant interests.

This entry places emphasis on the political implications of archaeological research on ideology. Nearly all scholarship on ideology is rooted in a critical philosophical tradition that views analysis of ideology as having contemporary political import, if not activist implications, so much of this archaeological scholarship consciously positions itself as a critique of contemporary ideologies as well as their historical precedents. Some archaeologists do that by stressing the many different ways humans have organized societies and power relations over millennia, others examine inequality in broadly defined complex societies, and still other scholars do it by tracing the concrete historical precedents of the contemporary world since the emergence of colonization. Regardless of context, ideology in any archaeological case study is significant as a critical framing mechanism that calls into question any representation of the relationship between consciousness and experience. By nearly any account, an archaeological focus on ideology provides a powerful framework to interpret the representation of inequality and relationships between materiality, structuring social systems, and representation of social life.

Key Issues/Current Debates/Future Directions

Relationship Between Power and Reality

Few archaeologists dispute the realities of inequality over the full breadth of complex societies, although that inequality encompasses a range

of contextually distinct power relationships ranging from profound exploitation to socially condoned systems of privilege and rank. Ideology is a body of beliefs that represents inequality and attempts to rationalize it or otherwise represent it in ways that aspire to reduce if not eliminate resistance. Some ideologies are dubbed "vulgar" in the sense that they are clearly rooted in one dominant group, obvious in their messages and intent, and likely visible to a vast range of people. However, attention here is focused on ideologies that are more accurately described as "non-vulgar" in their tendency to be marked as "common sense" assumptions beyond any critical apprehension. This breaks from the simplistic caricature of ideology simply as a vulgar "false consciousness" in which the masses are depicted as irrationally and more or less completely accepting the contrived class interests of the bourgeoisie.

The term ideology occasionally appeared in archaeological scholarship throughout the twentieth century, but it routinely referred to a general body of core beliefs or the broader world of ideas (cf. Eagleton 1991; Bernbeck and McGuire 2011: 45). Most contemporary definitions of ideology build on or are at least indebted to Marxian theory, where ideology is defined as an imagined relationship between consciousness and reality (Bernbeck and McGuire 2011: 17–19). In the 1980s a series of archaeological scholars began to use the notion of ideology to describe discourses of mystification, borrowing a belief most closely linked to Frankfurt School critical theorists. Critical theories tend to acknowledge that all perceptions of the relationship between reality and consciousness are mediated by ideology (Bernbeck and McGuire 2011: 24). Frankfurt School critical theory approaches scholarship on ideology as a contemporary intervention that raises consciousness of inequalities, reveals ideological fallacies, and fosters political action against such inequalities.

The most persuasive 1980s definitions of ideology firmly root it in relations of power and conflict and stress the connection between ideologies in the past and present. For instance, Mark Leone's archaeological analysis of ideology in the colonial Chesapeake borrowed from the French structural Marxism of Louis Althusser as well as Frankfurt School critical theory. Leone argued, following Althusser, that ideology was "those things that are taken by a society as given" (Leone 1984: 25). Those assumptions in Leone's formulation were class-interested representations of colonial elite that obscured the profoundly exploitative nature of inequality in the eighteenth-century Chesapeake. Leone argued that the elite's ideological representations of their power were designed to "naturalize and thus mask inequalities in the social order," with the intention to "disguise the arbitrariness of the social order, including the uneven distribution of resources, and it reproduces rather than transforms society (Leone 1984: 26)." Leone deployed this framework in an analysis of Chesapeake formal gardens and subsequently extended it to everyday commodities (Leone et al. 1987), arguing that the elite struggled to define artifacts of all scales in ways that reproduced inequality and their existing dominance. He argued that the gentry built Chesapeake formal gardens in the 1760s and 1770s to display their mastery of natural law and rationalize their material wealth and claims on political power. Some scholars are skeptical that nonelite accepted such representations of class power, and Leone (2005: 82) contends that it "did not matter whether slaves, free African Americans, or poor white people believed in the ideas on display, but it did matter whether middle- and upper-class people were impressed." Gardens viewed this way were mechanisms of ideological class consolidation rather than emulative models for the masses.

Leone asserted that such scholarship on inequality could be used to illuminate how contemporary capitalist inequalities have developed over more than 250 years. Many scholars examining ideology agree that self-reflection and consciousness promote activism against ideological inequalities. This sort of critical Marxian scholarship is often referred to as emancipatory. Dean Saitta (2005) argues that Marxism offers a powerful framework for an archaeology of tribal societies that is both explanatory and emancipatory; i.e., there is a concrete explanatory rigor in Marxism as well as a dimension that fosters critical

self-consciousness leading to change that might be considered emancipation. Saitta advocates examining tribal societies (e.g., Mississippians) as class societies in which surplus labor is appropriated in many different ways that range from collective to exploitative appropriation that was rationalized ideologically in many different forms. Yet he underscores that there is potential emancipatory impact in an archaeological picture of class in tribal societies that reveals the vast complexity in the ways societies produce and distribute social surplus. For Saitta, much of the power in an analysis of ideology is its power to erode widely accepted but largely unexamined assumptions about complexity and class by both archaeologists and contemporary constituencies.

Archaeologists have sometimes expressed skepticism that such ideologies were embraced by all consumers, casting doubt on the extent to which ideology determines everyday agency. Archaeological material culture certainly reveals widespread resistance to and breakdowns in ideological practices. Michel de Certeau (1988) stressed human agency within dominant ideology, laying a theoretical groundwork for archaeologists that resists the most deterministic notions of ideology. Certeau argues for "two logics of action" that he refers to as the strategic and the tactical. Tactics are opportunistic spontaneous actions, operating free in space, that subvert dominant strategic discourses. Tactics introduce plurality and individual creativity in the construction of meaning and action within an oppressive system, but they subvert that system through their ability to redefine what a commodity means and how it is used.

Archaeologists interested in such a picture of everyday life have often focused on the contradictions between ideological representation and everyday life practices. Archaeological scholarship on race and consumption, for example, has probed how African Americans resisted racist representations by literally buying into consumer culture. African Americans acquired commodities and embraced the role of consumer as a mechanism to defy racist stereotypes that assumed African Americans were not racially capable of participating in consumer culture (Mullins 1999). The challenge in such research is that the consumption of marginalized racial and ethnic collectives countered blatant ideological misrepresentations of those groups, but consumption demanded a commitment to wage labor inequalities, and goods brought with them social assumptions about behavior and identity that were not wholly empowering. James Symonds (2004) examines how archaeologies of urban working-class life in the United Kingdom, United States, and Australia collectively reflect the ways everyday life broke sharply from the poverty "myths" favored by contemporary observers and persistently misrepresented in heritage discourses. In similar ways, Rebecca Yamin's (2001) work in the Five Points neighborhood of New York City aspires to demonstrate how working peoples' lives were radically unlike the class-interested caricatures of social reformers who ostensibly hoped to contain poverty if not eliminate slums.

Most of these archaeologists share an interest in using archaeological material culture to bridge between past and present and counter historical narratives that reproduce if not perpetuate ideological distortions. Some scholars call this the archaeology of the "contemporary past," eliding the facile division between past and present and focusing on the ways historical narratives distort past experiences and their connection to the contemporary world. Laura McAtackney (2011), for instance, investigates the origins of Belfast, Ireland, in the seventeenth century, examining how walls have partitioned the city in particular ways over the subsequent centuries and remain boundary markers in the contemporary world. Since the 1960s, temporary walls have been used to divide ethnic and nationalist collectives in Belfast, often at the behest of those Belfast communities, but McAtackney argues that they pass largely ignored. Inelegantly known as "peace lines," these walls are ideologically designed to be expressions of control, and McAtackney examines how wall murals are used to both reaffirm

and challenge social and political control. McAtackney concludes that walls and their memorial murals permit communities to maintain identity distinctions, but at the same time they perpetuate longstanding tensions and hinder communication across lines of spatial and social difference. Such studies that aspire to bridge between past and present often illuminate ideologically laden heritage narratives and use materiality to erode dominant narratives. For instance, Adrian Myers' (2008) analysis of German concentration camps argues that the heritage of the camps inevitably cannot include the voices of the scores of prisoners who perished, and he advocates a material analysis to temper narratives that ignore the voices of the subaltern. Myers reasons that much of the material record of everyday goods reworked by prisoners or camp graffiti reveals the complicated range of ways prisoners resisted and negotiated imprisonment.

Archaeological scholarship on ideology aspires to underscore how society represents itself to its members, illuminating the ways that distinctions in privilege, power, and structural inequalities are explained. Many of these legitimizing and masking explanations are accepted very broadly in societies. But over time many of them erode as well, because rationalizations of inequality are constantly under fire and rarely accepted wholesale. Archaeology provides especially powerful material examples to illuminate how such ideological discourses are represented in symbolic and material form, revealing the ways various social agents accept ideologies as well as how some members reject ideological claims. The central thread in perhaps all the archaeological scholarship on ideology is its ambition to illuminate contemporary social inequality, sometimes by examining the many different ways past societies have represented inequalities and sometimes by revealing the very historical roots of contemporary ideological practice. It is difficult to fathom any scholar of complex societies and inequality ignoring the powerful framework ideology provides to analyze the representation of inequality and social life.

Ikawa-Smith, Fumiko

Makoto Tomii
Centre for Cultural Heritage of Kyoto University, Kyoto, Japan

Basic Biographical Information

Fumiko Ikawa-Smith is an anthropologist and prehistorian (Fig. 1). She is an Emeritus Professor at McGill University, Canada. She was born in 1930 and is the eldest daughter of the Buddhist historian Ikawa Joukei. Under the oversight of her mother, who was a high school teacher, Fumiko began studying English at an early age. She graduated from Tsuda College in 1953. Her graduate thesis was on critical essays by the British poet T. S. Elliot. Taking advantage of her proficiency in English, she was able to get a clerical position under ethnologist Oka Masao in the Department of Sociology at Tokyo Metropolitan University. She gained a strong interest in anthropology while assisting Oka with his lectures and research. In 1954 she resigned her position and began studying anthropology as a graduate student at the same university, with the focus on the ancient civilizations of Central America. At the same time, she met anthropologist Clyde Kluckhohn who was in Japan leading a series of seminars on American Studies. Through Kluckhohn, she gained direct contact with American anthropology, and with the help of Kluckhohn's wife, Ikawa took a leave of absence and obtained a Fullbright Scholarship to study at Harvard University. Though the study abroad was intended to last only 1 year, Ikawa has continued to study in the North America to this day.

Ikawa-Smith, Fumiko, Fig. 1 Fumiko Ikawa-Smith at Vladivostok in 2003. (© Robert E. Ackerman)

At Harvard, Ikawa initially aimed to specialize in Central America under Gordon Willey but switched to the study of Early Paleolithic cultures in East Asia after studying with Hallam Movius. At the same time, more material for the study of the Paleolithic in Japan was becoming available. In 1959, she married the prehistoric archaeologist Philip E. L. Smith whom she met at Harvard University. After the birth of their child, they moved to Canada where Philip was to teach at the University of Toronto. In 1962–1963, she accompanied Philip on his excavation in Egypt, and upon returning to Canada, she was responsible for organizing the artifacts. Following that, she served as a Lecturer in the Department of Anthropology at the University of Toronto. They moved to Montreal in 1966, where Philip taught at l'Université de Montréal while Fumiko at McGill University. After a few years of part-time teaching, she was appointed Assistant Professor of Anthropology in 1970, Associate Professor in 1974, and Professor in 1979. In the meantime, she obtained a doctorate from Harvard University in 1974 for her dissertation on the Early Paleolithic cultures of Japan. Before her retirement in 2003, she served as the Chair of the Anthropology Department, 1975–1980; Director of the Centre for East Asian Studies, 1983–1988; and Associate Vice-Principal (Academic) of the University in 1991–1996. In 2005, she was awarded the Japanese national decoration of The Order of the Sacred Treasure, Gold Rays with Rosette, for distinguished contribution to the cultural interaction between Canada and Japan. She is currently Professor Emerita at McGill University.

Major Accomplishments

One of Dr. Ikawa-Smith's greatest contributions to global archaeology was to provide a linguistic

bridge between Japan and the rest of the world in the decade that followed WWII. She played a major role in stimulating interest in the study of the Paleolithic period in Japan and emphasized Japan's unique capacity to fill in the knowledge gap between the Paleolithic period in China and the colonization of the Americas. Due to language barriers, little progress had been made in the 10 years following the first discovery of a Paleolithic site in Japan in 1949 at Iwajuku. It was in light of this that in 1960, along with Chosuke Serizawa, Dr. Ikawa-Smith coauthored an English language paper that introduced the available material for the study of the Paleolithic period in Japan and its position in East Asia (Serizawa and Ikawa 1960). This paper was highly regarded throughout the Americas. Because of her unique position, progress began to be made. Additionally, Dr. Ikawa-Smith also tried to bridge Japan's more historical approach to archaeology with America's anthropological approach. All of this was made possible by her archaeological education in the United States as well as her contact with Chosuke Serizawa, who encouraged a wider view of the world.

Dr. Ikawa-Smith's activities were not limited to spreading information from Japan to the rest of the world, however. Archaeology within Japan was stimulated by her paper in 1976 that introduced into Japanese Paleolithic studies the perspective of processual archaeology (Ikawa 1976). The work of her husband Philip, who tried to clarify the cultural origins of farming using an archaeological approach based on cultural anthropology, may have had an influence on her interest in the food habits of Paleolithic hunter-gatherers. In addition to this, Dr. Ikawa-Smith's work promoted discussions on research into the Paleolithic and Jomon periods in Japan from the perspectives of gender and national identity.

In 1973, Dr. Fumiko Ikawa-Smith organized the symposium "The Early Palaeolithic in Southeast Asia" to assist in disseminating information on East Asian archaeology to the West. Later, she worked alongside Gina Barnes and Sarah Nelson, both of whom also specialize in the study of ancient East Asia, to establish a research network for the study of East Asian archaeological data. In 1996, this group established the Society for East Asian Archaeology. Dr. Ikawa-Smith's broad range of international activities have had a profound influence on Japanese researchers, including but by no means limited to Junko Habu who graduated from McGill University with a doctoral degree in Jomon Culture and who now a professor in the Anthropology Department at the University of California, Berkeley.

Ikram, Salima

Salima Ikram
American University in Cairo, Cairo, Egypt

Basic Biographical Information

After double majoring in history as well as classical and Near Eastern archaeology at Bryn Mawr College (USA), Salima Ikram received her M. Phil. (in museology and Egyptian archaeology) and Ph.D. (in Egyptian archaeology) from Cambridge University (UK). Today she is distinguished university professor of Egyptology at the American University in Cairo. Although Dr. Ikram initially trained as a general archaeologist/Egyptologist, she moved to focusing on mortuary archaeology and archaeozoology, as well as being actively involved in rock art and museological projects.

Major Accomplishments

Dr. Ikram directed the Animal Mummy Project (Ikram and Iskander 2002; Ikram 2005 and 2015) and codirected the Predynastic Gallery Project, the Egyptian Museum Chariot Project (Veldmeijer and Ikram 2018), and the Amenmesse Project of KV10 and KV63, as well as being involved in several exhibitions at the Egyptian Museum in Cairo and consulting and working on exhibitions at other museums in Egypt, Europe, and the USA. She has participated in several excavations in Egypt where she has worked at sites from Alexandria to Aswan in various capacities. She has also worked in the Sudan and Turkey; in Turkey, she was chief archaeozoologist at the site of Kinet Höyük, ancient Issus. In Egypt, her focus has been on mortuary (Ikram and Dodson 1998; Dodson and Ikram 2008; Ikram 2013) and ritual sites, with an increasing emphasis on animal mummies (Ikram 2012a; 2005/2015), one of her specialties, and a subject that has enjoyed a renaissance as a scholarly and popular focus due to her research. The focus on animals also encompasses food and foodways in ancient Egypt (Ikram 1995; 2012b; 2013). Dr. Ikram also codirected the North Kharga Oasis Survey in Egypt's Western Desert (Rossi and Ikram 2018) and directs the North Kharga Oasis Darb Ain Amur Survey (Ikram 2009a, b). This project has widened her interests to include environmental archaeology, rock art, and cultural heritage issues (Ikram the protection and presentation of sites in Egypt's Western Desert, with a pilot heritage management project being carried out at the site of Qasr el-Lebekha. In addition to archaeological and museological work, she has taught at the American University in Cairo since 1995 and has been instrumental in establishing an M.A. program in Egyptology and Coptology there. She is also very interested in engaging younger audiences and has written a series of children's books (Ikram 1997a–c, 1998, 1999; Bowditch and Ikram 2018)

Ileret Footprints

Matthew R. Bennett
Bournemouth University, Poole, UK

The Koobi Fora Formation, located in the Turkana Basin of northern Kenya, is one of the richest and most famous hominin fossil beds in east Africa (Harris et al. 2006). Two footprint sites have been excavated in this basin to date one close to Ileret and a second slightly younger site close to Koobi Fora.

The tracks close to the village of Ileret data from ~1.52 Ma and were reported in 2009 within the Okote Member of the Koobi Fora Formation (FwJj14E; lat 4°18′ 18′ 44″N, long 36°16′ 16′ 16″E; Bennett et al. 2009). They are younger than the mid-Pliocene (3.66 Ma) tracks at Laetoli (Leakey and Hay 1979) but are the oldest in the world attributed to the genus *Homo*. This site has been excavated since 2006, and during 2013/2014 additional satellite excavations were dug (Roach et al. 2016; Hatala et al. 2016a, 2017). The main site consists of an eroding bluff of sediment capped unconformably by Holocene sediments (Galana Boi Formation; Feibel et al. 1989). Within the main site, two hominin track-bearing horizons are known with more isolated tracked horizons between. The sedimentary succession consists of over 9 m of fine-grained, normally graded, silt and sand units (0.1–0.5 m) between thicker (0.5–2.0 m) paleosols. Isaac and Behrensmeyer (1997) suggest that the sediments around Ileret form part of a low-energy fan delta with numerous seasonally dry distributaries draining into a more stable lake body that may have gradually transgressed over at least part of this area (Fig. 1). There is no clear evidence of this transgression at FwJj14E, and track-bearing horizons consist of fining-upward waning sheet flood deposits in which course sand drapes underlying deposits (and/or the previous flood cycle) fining upward to fine silts which appear to have been emergent but are not unduly desiccated. They may be representative of either crevasse splays or more simply over-bank floods on a low-lying flood- or delta plain. These deposits are interbedded with thicker more massive fine sand units which show evidence of paleosol development. The paleosols are indicative of wet-dry seasonal conditions as described by Wynn (2004) more generally within the Koobi Fora Formation. Within this succession, there are three re-worked volcanic ashes; the upper ash (Northern Ileret Tuff) forms a prominent landscape benchmark that correlates with nearby sites containing traces of hominin activity including cut bones. The ash layers have been

Ileret Footprints, Fig. 1 Sedimentology at FwJj14E from Bennett et al. (2009) and paleogeographical reconstruction based on the work of Isaac and Behrensmeyer (1997)

correlated geochemically to dated tuffs within the Turkana Basin thereby providing an age of 1.51–1.52 Ma for the upper tuff and 1.53 Ma for the lower tuff (Bennett et al. 2009).

The original hominin tracks were described by Bennett et al. (2009) and subsequently by Dingwall et al. (2013) and most recently by Hatala et al. (2016a, 2017) who also records additional hominin tracks found at the satellite excavations. There is a broad consensus that the hominin tracks were made by *Homo erectus*, although the possibility of other track-makers such as *Paranthropus boisei* cannot be excluded completely (Dingwall et al. 2013; Hatala et al. 2016a). Dingwall et al. (2013) estimates walking speeds of between 0.45 and 2.2 ms^{-1} made by heavy (41.5–60.3 kg), tall individuals (1.526–1.858 m).

Modern human footprints reflect the distinct anatomy and function of the human foot, which is characterized by a fully adducted hallux, large and robust calcaneus and tarsal region, a pronounced medial longitudinal arch, and short toes. Footprints reflect the pressure distribution as the foot makes contact with a substrate mediated by the sediment's geomechanical properties (Bates et al. 2013). During normal walking, the heel makes first contact with the ground. This is followed by contact with the lateral side of the foot and metatarsal heads, after which weight transfers medially along the ball of the foot with peak pressure under the medial metatarsal heads, and finally ending with toe-off pressure under the hallux. The distribution and pattern of depth within a footprint generally reflects this typical pattern of weight transfer, although will appear different when corrections are being made for balance. This allows biomechanical inferences to be made from sets of footprints. The prints at Ileret have (Bennett et al. 2009) (1) a well-defined hallux which is in line with the lateral toes, (2) visible lateral toe impressions that vary in depth of indentation, (3) a well-defined ball beneath the first and second metatarsal heads, and (4) and a visible instep reflecting a medial longitudinal arch. The angle of hallux abduction, relative to the long axis of the foot averages 14° compared to 8° for modern prints and 27° for the Laetoli prints (Bennett et al. 2009). The morphology of the Ileret prints suggests that the feet of these hominins had functional medial longitudinal arches and a modern humanlike toe-off mechanism and therefore operated in a biomechanical fashion akin to that of modern humans (cf. Hatala et al. 2017).

The significance of the Ileret footprints lies in the fact that they provide evidence of a modern foot function on one side of the transition from the *Australopithecus* to *Homo* genus. This transition is one of the most significant events in human evolution (McHenry and Coffing 2000; Pontzer 2007; Ruff et al. 1993): longer lower limbs lowered energetic cost (Pontzer 2007); archaeological indications of activity occur in a much wider variety of ecological settings; and there is evidence of transport of resources over long distances. Together these are consistent with a transition to endurance walking and running. Recent work involving the Ileret tracks by Bennett et al. (2016) suggests that foot function did not change across this evolutionary transition, although not all parties agree with this interpretation preferring a more primitive function for the earlier Laetoli tracks (Hatala et al. 2016b).

Recently, Hatala et al. (2016a) have argued that the sub-parallel nature of the track at Ileret, and their consistently large size which is attributed to them being males, coupled with similar levels of track deterioration implies near-simultaneous imprinting by groups hunting in coordinated groups. As such, they claim evidence for social organization within *Homo erectus* which is consistent with evidence from elsewhere in the East African Rift of ambush hunting (Kübler et al. 2015). This interpretation is complimented by the work of Roach et al. (2016) who discuss the wider implications of the animal tracks present and advance a paleoenvironmental interpretation. Their interpretation is based on the assumption that the tracks are ephemeral and deteriorate quickly after formation, and therefore tracks with similar levels of preservation can be assumed to have been imprinted either simultaneously or in close temporal proximity. While they do not publish a detailed taxonomic list, nor describe the tracks assigned to each taxon in detail, they do state that the most frequently recovered tracks are Bovidae and Suidae, hippopotami, crocodile, and

various water birds which they suggest are indicative of a stable water body (Lake Lorenyang; Feibel et al. 1989). No sedimentological data is advanced to confirm this however. They use the contrasting orientation of hominin and animal track directions to suggest that the hominins were moving shore-parallel, a strategy that is consistent with predator/hunter behavior. In particular they contrast track abundance/density with that obtained from skeletal remains (Fig. 2) and point to the fact that hominin tracks occur much more frequently in the record than is consistent with the skeletal remains recovered. They suggest that this is due to frequent imprinting as groups of *Homo erectus* moved along the former lakeshore in hunting groups. It is an interesting hypothesis although it depends on the contemporaneity of the tracks and that the group occupying the area may have either transited just once or took a different path each time. A single or small number of

Ileret Footprints, Fig. 2 Faunal diversity based on vertebrate tracks and bone walks modified from Roach et al. (2016). (Animal images are from http://phylopic.org/)

track-makers could also build up a similar set of tracks. While the footprint maps within Hatala et al. (2016b) show a series of sub-parallel tracks, they overlap and show movement in both directions. Cross-cutting trackways have been described previously (Bennett et al. 2009; Dingwall et al. 2013). The leap to social organization and to predominantly male hunting groups may be a bit of a stretch on the available evidence. Nonetheless, it is an exciting and interesting use of tracks and complements recent work in Ethiopia (Altamura et al. 2018)

In conclusion, it is worth noting that Ileret is one of two footprint sites in the Turkana Basin. The second footprint site 45 km to the south of Ileret was first reported in Behrensmeyer and Laporte in 1981 (Behrensmeyer and Laporte 1981) and consists a single trail of poorly defined prints which were imprinted subaqueously (GaJi10; lat 3°44′ 44′ 15″N, long 36°55′ 55′ 48″E). The footprint surface occurs below a prominent tuff, sampled and correlated by Bennett et al. (2009) to the Akait Tuff and dated to 1.435 Ma. Re-excavation of these prints by Bennett et al. (2009) uncovered four of the original seven prints, and the two best-preserved examples are comparable to those at FwJj14E. Further excavation in adjacent areas has so far failed to uncover additional hominin footprints but has revealed an extensive surface of animal tracks dominated by the prints of swimming hippopotami (Bennett et al. 2014). The presence of two sites with the Turkana Basin hints at the potential for further discoveries in the coming years.

Imaging Techniques in Bone Analysis

Gerald Conlogue[1] and Mark Viner[2,3]
[1]Bioarchaology Research Institute, Quinnipiac University, Mount Carmel, CT, USA
[2]Cranfield Forensic Institute, Cranfield University, Shrivenham, Wilts, UK
[3]Institute of Dentistry, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, UK

Introduction

The main medical radiological imaging techniques used for forensic examination of skeletal material may be summarized as follows:

Radiography: The term radiography is generally used to describe a static or "still" two-dimensional image produced by means of a single exposure to X-rays (an energy form of ionizing radiation). Such images are now usually recorded and stored digitally but were previously recorded photographically on X-ray film.

Fluoroscopy: The term fluoroscopy is used to describe a two-dimensional image directly visualized in real-time motion produced by a continuous exposure to X-rays.

Tomography: Tomography employs a moving X-ray tube and image receptor to create an image of a plane or "slice" within an object. Originally developed in the 1930s to overcome the limitations of radiography as a two-dimensional imaging method, the application of digital detectors and computer science led to the development of:

Computed Axial Tomography: CAT or CT scanning employs a computerized X-ray machine that uses an array of photoreceptors to detect minute differences in attenuation of X-rays emitted by an X-ray tube as it rotates around the body or body part. A computer generates an image of the body part in the axial or cross-sectional plane, and modern multi-detector (MDCT) scanners permit multi-planar, multidirectional sectional images to be displayed and/or reconstructed as three-dimensional images.

Definition

The examination of skeletal material should be divided into two general categories: *macro-* and *microradiography*. Historically, plane radiographs were examined by placing the film on an illuminator or viewing box. A hand lens may have been used to magnify a particular region of interest, but generally the structures under consideration where large enough to be easily demonstrated without magnification. Today, the resolution available with computed tomography (CT) is sufficient to provide two-dimensional sections and three-dimensional images that also do not require magnification. For the purpose of this chapter, images that can be viewed without the need of magnification have been categorized as *macroradiography*.

Microradiography has a long history. With contact microradiography, the object under

examination, usually less than a centimeter in diameter, is placed directly on the image receptor, and the resulting image is primary viewed under magnification (Conlogue and Marcinowski 1986). Today, micro-CT has expanded the possibilities and eliminated the need to physically section an object in order to demonstrate internal structure.

Application of Macroradiography Techniques

Radiological imaging has the advantage of enabling the examination of remains in a variety of states of decomposition from fully fleshed to completely skeletonized. As such, it affords the opportunity to obtain a considerable amount of data without the need to clean and/or completely deflesh the remains. It provides the investigative team with a rapid method of triage and classification by answering a number of fundamental questions:

Establishing Context

Human Versus Nonhuman

In most cases involving nonhuman (animal) bones, a simple visual examination is all that is necessary for the trained anatomist or forensic anthropologist (or osteologist) to determine nonhuman characteristics. In some cases, however, the most distinctive parts of the bones, the articular surfaces, may be missing due to fragmentation, decomposition, or animal activity, and in such cases radiographic examination of the bone structure and trabecular pattern can be useful to determine human from nonhuman remains (Brogdon 2011a; Chilvarquer et al. 1987).

Recognition of Commingling

In cases involving large amounts of fragmented remains, remains may be commingled and mixed with large amounts of debris and artifacts. Physical examination of such remains, particularly in cases involving exhumation or fire damage where there is a uniformity of discoloration of all samples retrieved, is both difficult and time-consuming. In such cases, radiological examination can prove useful to the forensic pathologist and/or anthropologist both in determining the presence of one or more individuals but also in identifying and locating small body parts, which may otherwise be overlooked in the absence of a thorough and time-consuming fingertip search.

Location and Retrieval of Artifacts/Evidence

In the same way, X-ray imaging can be utilized to detect and retrieve various objects that have been recovered together with the remains during excavation or body recovery. This can be helpful especially when body fragmentation is extensive and has proved particularly useful in mass fatality incidents (Viner and Lichtenstein 2011) or where the body has been exhumed. In the latter case, it may also be useful to radiograph the associated debris excavated with the body in order to detect small items such as jewelry or other personal effects which may have become disassociated from the body during decomposition – a technique referred to by Wessling as "The third method of Sieving" (Tonello 1998; Viner 2008; Wessling and Loe 2011) (Fig. 1).

Human Identification

Establishing the Biological Profile (Age, Sex, Stature, and Ancestry)

In the same way that a physical examination of the defleshed skeleton allows the forensic anthropologist and/or odontologist to estimate age at the time of death, so can skeletal radiography deliver the same information in the case of less decomposed remains by analysis of the state of maturation of dental structures, ossification sites, and degenerative changes. Similarly, radiologic examination of the pelvis, skull, and mandible can assist with the differentiation of sexes in cases where direct physical examination and measurement are not possible (Brogdon 2011a).

Estimations of stature are often made by direct measurement from unfleshed human remains. The same measurements can be made radiographically, provided that correction for magnification

Imaging Techniques in Bone Analysis, Fig. 1 A portable direct digital X-Ray system being used on-site to examine remains. In this particular case, the unit is located in the back of a van and is being powered by a small generator. (Image provided by kind permission of Reveal Imaging Ltd)

is made (Brogdon 2011a). This can either be achieved by means of an adapted radiographic technique, applying a simple correction factor or utilizing modern imaging techniques such as CT scanning and digital radiography. CT scanners and digital X-ray systems can be calibrated to undertake this correction calculation automatically, thus allowing measurements to be made directly from the image. In the case of CT scanning, a scanogram is performed using the scanner to undertake an automated version of the manual process described above. Digital X-ray machines using a slit beam can also be used to take direct measurements, and many other direct digital X-ray machines can be calibrated so as to render accurate anatomical measurements from the resultant images.

Similar methods to those used by forensic and physical anthropologists to make an assessment about ancestry from skeletal remains can be applied radiographically with fleshed remains. In particular, examination of the skull and mandible, the distal end of the femur, and the ratio of long-bone length can be useful in determination of population ancestry (Brogdon 2011a).

Positive Identification of Individuals by Comparison of Antemortem and Postmortem Radiological Data

Radiological identification of human remains requires specific and unique findings on postmortem images to be matched exactly with antemortem images of the individual. In some cases, identification can be made from a series of relatively common or nonspecific pathological anatomical changes that appear in identical locations in ante- and postmortem images. In other cases, a single unique feature is sufficient (Brogdon 2011a).

Medical imaging has long been used for the identification of human remains and is well documented. Radiology is used extensively in anthropological and odontological assessment of postmortem and antemortem radiographs, records, or other images for concordance as they represent an excellent source of data for comparison of anatomical features (Fig. 2). Many specific cases have been reported in which radiology has played the leading role in the identification of human remains (Kahana and Hiss 1997; Viner and Lichtenstein 2011).

Analysis of Injuries

Interpretation of Trauma

Radiology can be used to assist in determining the manner of death or the extent and mechanism of trauma. In cases of extensive trauma, individual demonstration of all fractures present after a fatal accident may be a time-consuming process, and radiological examination simplifies the procedure. In addition, some fractures are difficult to demonstrate and are more adequately demonstrated using radiological methods such as X-ray or CT scanning.

Radiological examination may yield far more than simply demonstrating the presence of fractures. It may be able to demonstrate the nature of

Imaging Techniques in Bone Analysis, Fig. 2 Healed fractures such as this fracture of the tibia can enable an identification to be made via comparison of antemortem and postmortem images. Two projections of any fracture site, in the anterio-posterior (**a**) and lateral (**b**) should be made during post mortem examination. These are standard projections that are used in orthopaedic radiography to assess the healing fracture and post-mortem films can thus be compared with any ante-mortem images that may be available

Imaging Techniques in Bone Analysis, Fig. 3 "Defence fracture" of the ulna caused by blunt force trauma to the forearm. (Image provided by kind permission of the United Nations International Criminal Tribunal for the Former Yugoslavia)

the trauma that caused the fracture by determining the direction and impact of the force and in some cases may enable a fracture that has been caused by an assault to be differentiated from trauma sustained following an accidental fall (Fig. 3). MDCT scans and surface scanning techniques may also allow three-dimensional modeling to identify directions of impact and size and shape of weapons used to inflict trauma (Nather et al. 2011; Buck et al. 2011).

Radiology may also be of significance in proving the infliction of injury at various times by demonstrating healing and fresh fractures, and such evidence is essential to the concept of systematic abuse or torture (Brogdon et al. 2003). In some cases it may be particularly useful to identify perimortem trauma as fresh callus formation may be used for stable isotope analysis to determine the geographic region in which the deceased was living in the time leading up to their death by means of analyzing the bone mineral content.

The most obvious use of X-rays in cases of suspected homicide is to demonstrate the presence of bullets and other missiles within the body. Projectiles may be found some considerable distance away from the entry site, and radiography can be used to locate these. The deployment of a dynamic imaging method, such as fluoroscopy, will accelerate the process of retrieving ballistic material. This is particularly true when the body is partially decomposed and subjected to fire or has been exhumed. In such cases, physical examination

Imaging Techniques in Bone Analysis, Fig. 4 Lateral (**a**) and submento-vertex (**b**) projections of the skull reveal ballistic traces within the skull in the area of the left orbit, confirming the path of a bullet from its entry site in the occipital bone to its exit through the left orbit (**c**). (Image provided by kind permission of the United Nations International Criminal Tribunal for the Former Yugoslavia)

and location of ballistic material is often hindered by uniform discoloration and can be a time-consuming process. Even if the projectile is recovered without the aid of radiography, fragments of bullets or of bomb casings or contents can easily be missed in an unaided dissection, and important information for the ballistic expert may be lost.

The determination of other causes of death is also assisted by the use of X-rays. Of significance is the radiography of the larynx in cases of strangulation in which fractures of the thyroid cartilage or hyoid bone can be demonstrated, particularly if the cartilages are calcified (reference), a process which increases with age. Radiology has proved particularly useful in assessing and documenting trauma in mass fatality incidents (Alexander and Foote 1998; Harcke et al. 2002; Viner and Lichtenstein 2011), and radiological methods have also been employed extensively in the investigation of war crimes and human rights abuses involving the exhumation of buried human remains where radiology will assist in the location of ballistic material, the evaluation of gunshot and/or explosive injuries, and the investigation and documentation of any antemortem trauma (Tonello 1998; Viner 2008) (Figs. 4 and 5).

Key Issues and Examples of the Application of Macroradiography Techniques

For all its disadvantages, film is still the recording media of choice under certain circumstances, e.g., a sample consisting of a few small objects. Choices of recording media are not limited to medical radiographic film, and indeed, film intended for industrial applications has several advantages over its medical counterpart. Although it requires more radiation, the film provides greater resolution and a longer scale of contrast, more shades of gray. In addition, since X-ray and light are both forms of electromagnetic radiation, various types of sheet film or paper employed in

Imaging Techniques in Bone Analysis, Fig. 5 Initial x-ray examination of human remains revealed a ballistic fragment in the spine. This was further documented and localised by radiography of the lumbar vertebra prior to retrieval. Localisation is facilitated by two projections taken at 90°; in this case supero-inferior (**a**) and Lateral (**b**) projections. (Image provided by kind permission of the United Nations International Criminal Tribunal for the Former Yugoslavia)

Imaging Techniques in Bone Analysis, Fig. 6 A severed bound foot of a Chinese woman from the Mütter Museum, College of Physicians of Philadelphia, Philadelphia, Pennsylvania recorded on Polaroid Type 804 film

photography are capable of providing satisfactory results. Until 2009 when manufacturing ceased, Polaroid™ 8″ × 10″ types 804 and 805 produced excellent results (Fig. 6). Ilford™ photographic paper loaded in a screen cassette and in a non-screen film holder both provided images with exceptional detail resolution and contrast (Conlogue and Beckett 2010).

With only a few images to process, large tanks normally used to manually process exposed film are not necessary. Photographic trays typically employed to process photographic prints can serve to process radiographic film as large as 14″ × 17″ (35.6 × 43.2 cm). For smaller size film, disposable plastic containers are inexpensive and available a large food or discount stores.

When the size of the sample or object to be examined is large, digital radiography becomes the more realistic option for several reasons. Firstly, manually processing more than a few large format (14″ × 17″ [35.6 × 43.2 cm]) films is a cumbersome undertaking. Secondly, a large film requires at least 5 gallons (22 l) of water to be considered thoroughly washed prior to drying.

In the medical arena, film has gradually been replaced by a digital recording media. Although the initial outlay is expensive, the advantages of the digital approach, such as post-processing of

the image therefore eliminating the need to repeat an exposure, have reduced patient exposure and increased patient throughput.

Digital radiography can be divided into two categories: direct digital radiography (DR) and computed radiography (CR). With DR, the imaging plate is either directly or remotely connected to a computer. Within seconds of the exposure, the image will appear on the computer monitor. In most systems, the X-ray unit is an integral component and therefore increases the overall cost. In the case of CR, any X-ray source can be used. Following an exposure, the imaging plate is placed into a device called a reader in which the imaging plate is scanned by a narrow laser beam that transforms the X-ray energy trapped within the surface of the plate into visible light and then to an electrical signal and finally an image on the computer monitor. Because the CR process has several steps, the resulting image may be as long as 2 min following the exposure.

Each system has advantages and disadvantages. The principle advantage of DR is the short duration between the exposure and appearance of the image. With less time between exposures, more images can be acquired in a day. For example, during a 9-day radiographic examination of skeletal remains under St Bride's Church in London, a total of 1,192 exposures were made, averaging 132 images per 6-h day or 22 exposures per hour. Similar types of studies using film had a much lower number of images per day. In Guanajuato, Mexico, films were taken of mummified remains in the *Museo de Momias* and transported three times a day to be processed at a local hospital located 30 min away. Working 8-h days over a 5-day period, a total of 196 radiographs were taken. Unfortunately, either the temperature of the chemistry in the automatic processor or a fluctuation of the electricity supply to the X-ray unit changed between the second and third batch of film because the entire third batch had to be repeated.

Another advantage of DR is that the object does not need to be moved to process the image. If the image shows a less than optimal position, a slight adjustment of the object can be achieved within a minute or so of the first exposure. Even when a study is conducted in an imaging facility with an automatic processor in the next room, a repeat of a radiograph taken with film would take much longer. In order to process the image, the object would need to be removed from the cassette. The cassette is then brought to the darkroom and the film placed into the processing unit with at least a 90 s wait until the processed image can be examined. If a repeat exposure is necessary due to poor positioning, it is less likely to be as easily corrected because the object was removed in order for the film to be processed.

A third advantage is demonstrated if a repeat is necessary due to a poor exposure setting. Since the raw data from the plate is digitized prior to processing by the computer, algorithms within the computer software can manipulate the data, within limits, to insure an acceptable image.

There are several disadvantages of a DR system, the principle drawback being cost. As previously indicated, most systems require the X-ray source be integrated into an entire DR system. In addition, the X-ray tube support that is designed for mobile radiography will add about another 80 lbs (36 kg) to the overall weight of the system. If the study is in a remote location, the additional weight can become problematic. Another cost-related disadvantage is the expense for replacing a damage imaging plate. Once the plate is damaged, no more images can be acquired until the plate has been replaced.

The DR system cannot permit a multiple exposure to be taken on a plate before it is processed. The system is designed to transmit the data as soon as an exposure has been taken. However, there are certain situations when multiple exposures are necessary. If the object to be radiographed is sufficiently dense to require an exposure that exceeded the maximum output of the X-ray unit and film is the recording media, multiple exposures can be taken with an adequate interval between exposures to insure that the X-ray tube will not be damaged. Multiple exposures may also be necessary in a situation where the distance between the X-ray source and the image receptor is great. Because the X-ray beam diverges from the source, if the distance is doubled to the image receptor, four times the exposure

is required. In a study of 18 mummies at the Detroit Science Museum, a 168 in. (427 cm) distance between the X-ray source and the image receptor was required for the X-ray beam to cover the entire individual. Since the study area was in a warehouse, there was no restriction due to the ceiling height, and the X-ray tube was attached to the tines of a forklift (Fig. 7). The resulting radiographs, recorded on film, were digitized and electronically "stitched together" to produce a single image of each mummy.

Computed radiography (CR) is the less costly alternative to DR, and the plates can be used when multiple exposures are needed. An additional advantage is that there are CR systems for both medical and industrial applications. The medical systems require less radiation to produce a satisfactory image; however the industrial systems not only have increased resolution but also more algorithms or mathematical manipulations of the raw data.

Imaging Techniques in Bone Analysis, Fig. 7 The tines of a fork lift truck were used to support the x-ray tube (A) above the mummy (B) to achieve the distance necessary to radiograph the remains in a single radiograph

A single "seamless" image of a mummified individual in the Mütter Museum at the College of Physicians in Philadelphia, Pennsylvania, provides an excellent example. To image the individual known as the "Soap Lady mummy," four Fuji™ industrial CR plates were taped to a sheet of chipboard. Once in place, the plates were exposed to fluorescent light for 30 min to insure there was no residual energy on the plate surface, and then the board with the attached plates was covered with black gardening plastic. A total of 12 exposures were made using 86 kVp at 34 mAs. In a make-shift darkroom, the plates were removed from the board, placed into a light-tight box, and transported for processing approximately 200 miles to the Fuji™ Research and Development testing facility in Stamford, Connecticut. The images were downloaded onto a DVD and later stitched together using a photographic enhancing program to produce a single image of the entire mummy (Conlogue et al. 2010).

This example demonstrates another advantage of the CR approach. The plates can be taken to a location exposed and then transported to another site to be processed by the reader. Less than 24 h elapsed between the exposures in Pennsylvania and the time the plates were placed into the reader in Stamford, Connecticut. In another study, a Konica™ medical CR plate was used to image a lateral skull of a formalin-preserved cadaver where the arterial vessels were injected with barium- and gelatin-based contrast media. Two plates were exposed using identical technical factor: one was processed immediately and the other approximately 2 weeks later. Although visually the images appear almost identical, the numerical representation of the exposure, known as the "S" value, indicated the plates were losing the charge over time (Fig. 8).

The ability to correct a poor exposure is incorporated in both DR and CR algorithms that are used to generate an image. An example is demonstrated by an underexposed lateral chest image of a mummy captured on a Fuji™ industrial radiography CR plate (Fig. 9). If film had been the recording media, the only option would be a repeat. If this was the appearance of a batch of

Imaging Techniques in Bone Analysis, Fig. 8 Two lateral skull projections of a formalin preserved individual with the arterial system filled with a barium gelatine compound. An S value of about 200 indicates a satisfactory exposure (**a**). As the S value increases, it indicates an under exposure (**b**). However, the algorithm employed to process the data will make adjustments, within limits, to insure the resulting images look similar

Imaging Techniques in Bone Analysis, Fig. 9 (**a**) A lateral chest radiograph of a mummy identified as George/Fred that was processed 20 days following the exposure. (**b**) The original data reprocessed to produce an acceptable image

films processed, the entire group would need to be repeated and possibly an entire day of work lost.

Everything discussed to this point represents two-dimensional imaging. The primary disadvantages of this approach are superimposition of structures and magnification. Because of superimposition, at least two images at right angles to each other must be obtained to determine the relative position of structures within an object. Objects, such as skulls, necessitate multiple images in order to understand complex internal structures. Similarly magnification is inherent to all radiographs regardless of the recording media. The further a structure is away from the image receptor, the greater the magnification. Therefore, without knowing the distance an internal structure is above the receptor, it is not possible to obtain an accurate measurement of the structure. The process is more complex if the internal structure of interest is not parallel to the image receptor. The portion of the structure closer to the imaging plane will be less magnified than regions farther away. This will result in unequal magnification, more correctly termed distortion. Since it is very difficult to get an internal structure parallel to the image receptor, distortion of some structures within a complex object is always present in a two-dimensional (2D) imaging.

In the 1930s a technique was developed in an attempt to eliminate or at least minimize

this problem of creating a two-dimensional image of a three-dimensional object. The approach, termed tomography, involved an equipment modification that incorporated a coordinated movement between the X-ray source and the image receptor. In the most basic configuration, during the exposure, the X-ray tube moved in a linear arc opposite in direction from the motion of the image receptor, originally film (Fig. 10). A plane was created, within the patient and parallel to the surface of the film, termed the focal plane. Structures in the plane were in focus whilst those above and below the focal plane were blurred. Prior to the next exposure, by raising or lowering the patient, different levels within the individual were brought into the focal plane and visualized (Fig. 11a, b). Tomography became an important imaging modality until the advent of another tomographic innovation, computed axial tomography (CAT) scan, that replaced film with a detector and processed the imaging data through a computer to create sections perpendicular to the table top.

Imaging Techniques in Bone Analysis, Fig. 10 Basic tomography relied on appositional movement of the X-ray tube and image receptor to create a focal plane within the patient

Within the past decade, tomographic principles have been incorporated into digital imaging for various clinical applications. One such unit is the XPERT® 80 Cabinet X-ray System developed by Kubtec Medical Imaging. This unit is a cabinet tomosynthesis radiographic system, designed to examine breast tissue in the laboratory following surgery to compare the images to the preoperative mammogram and determine the effectiveness of the operative procedure. As such, it is a self-contained lead-lined unit and requires no special installation, and because of the 50 μm focal spot size and the ability to generate both 3D and 2D images, the system has nonclinical applications in various scientific disciplines including bone analysis in anthropology and forensics. To

Imaging Techniques in Bone Analysis, Fig. 11 (**a**) A posterior-anterior, PA, chest with a cavernous tubercular lesion revealed in the right lung (yellow arrows). (**b**) A tomographic image more clearly demonstrating the cavity (yellow arrow) with the blurring of structures above and below the lesion

accommodate this application, Kubtec produced another model, the Parameter® 3D Tomosynthesis System, and this was employed in the following two studies.

The first involved a demonstration of the development of dentition in fetal skulls and compared these to known gestational ages (Fig. 12a, b). Without repositioning the skull, all the developing dentition, parallel to the image detector, was easily demonstrated by scrolling through the slices. The systems primary limitation was the small size of the 5 × 6 in. (12 × 15 cm) detector.

The second study examined the ability of the system to detect a simulated occult fracture in a fetal pig. In cases of child abuse, occult fractures can be difficult to demonstrate with lower-resolution, clinical computed radiography (CR) or direct digital radiography (DR) systems. In order to mimic the condition, a small incision was made in a fetal pig, and two ribs were cut using scissors (Fig. 13a). The composite image not only revealed the fractures but also exhibited the vinyl material injected into the arteries and veins of the fetal pig (Fig. 13b). The latter provided an excellent example of the wide latitude of a digital imaging system, and the 1.0-mm-thick slice clearly visualized the rib fracture (Fig. 13c). Finally, since the photograph and the slice demonstrating the fracture can be electronically superimposed, it was possible to see the relationship between the incision and the rib fractures (Fig. 13d).

Computed tomography eliminates both superimposition and magnification. Identical to DR and CR, because the data are processed by a computer, the appearance of the image can be modified by post-processing manipulation. However, unlike all 2D radiography, where the X-ray beam covers a large area, for example, a 14 × 17 in. (35.6 × 43.2 cm) plate, the beam emitted from the CT X-ray tube is very restricted or collimated, in certain systems as small as 0.5 mm, to expose only a narrow array of detectors. The result of this highly collimated beam is the ability to differentiate tissue with only slight differences in density, such as white and gray matter of the brain.

Possibly one of the most important aspects of CT is that the data is quantitative rather than qualitative. Prior to being displayed, all the data is standardized to a known density, and water is assigned a CT number, also termed a Hounsfield Unit (HU), of "0". All tissues less dense than water have a negative value. Air has an assigned value of −1000. Tissues more dense than water have a positive value. With this innovation it is now possible to characterize tissue and get the same CT number regardless of the unit it was scanned on. On a living patient, a decrease in cortical bone density might suggest osteopenia.

Imaging Techniques in Bone Analysis, Fig. 12 (**a**) A composite image created by stacking all the sections acquired with the Parameter® 3D Tomosynthesis System. Note the high resolution in the developing membranous bone of the skull and ossification of the developing crowns of the dentition within the crypts of this 32–36-week gestation dry fetal skull. (**b**) A 1.0-mm-thick section elimination the superimposition of the surrounding structures to more clearly demonstrate the developing crowns

Imaging Techniques in Bone Analysis, Fig. 13 (**a**) Since the Parameter® 3D Tomosynthesis System is equipped with a camera, it was possible to document the site of the incision (arrow). (**b**) The fractured ribs (yellow arrows) were seen on the composite image in addition to the vinyl material injected into the aorta (red arrow) and superior and inferior vena cavae (blue arrow). (**c**) The 1.0-mm-thick slice that included the fractured ribs clearly demonstrated the fractures (arrows) eliminated the superimposed structures. (**d**) The photograph of the incision (red arrow) superimposed of the tomosynthesis slice revealing the fractures (yellow arrows)

Operational Considerations for the Use of Radiography Techniques in the Archaeological Context

The value of radiography in the examination of mummified and skeletal remains is indisputable. Over the past several decades, radiography has become more available due to technical innovation in hardware development which has resulted in plane radiography tubes as small as 10 kg. In addition, digital imaging receptor systems have replaced film, and software development has enabled post-processing image manipulation. The latter has virtually eliminated repeat radiographs due to improper exposure factor setting. In the clinical setting, these advances have resulted in the ability to examine more patients per unit time, a concept termed patient throughput. However, all these advances have been created specifically for the clinical setting with the focus on reducing patient dose while sacrificing image resolution. Unfortunately, when not dealing with living tissue, the opposite is the objective: maximize resolution with little regard for dose. The latter is particularly true since it has been documented that radiation dose does not affect the recovery of ancient DNA (Fehren-Schmits et al. 2016; Ziegler et al. 2013).

That concept of throughput can be easily integrated into anthropological field studies that

utilize radiography. Incorporating this clinical concept will not only increase the productivity, making the use of radiography more cost effective, but also increase the resolution of the acquired images. In order to do so, four specific requirements must be met as outlined below. These are followed by an example of a study of mummified remains in Gangi, Sicily, in 2015.

1. A radiographer, an individual schooled in the science and art of radiography, should be brought in during the early stages of project development. As the hardware and software innovations, including icons for specific body parts, have been developed and configured for living individuals, the radiographer, acting as a consultant, will need to modify or adapt these preset protocols for the specific needs of the project.
2. An X-ray source/sources should be selected by the radiographer consultant. It must be lightweight making it easy to manipulate. The support for the X-ray source should be specifically created for the intended application of the study.
3. In imaging receptor should also be selected. As discussed previously, digital imaging receptors have replaced film in radiography and the advantages and disadvantages of the two categories of digital systems, DR and CR, considered. However, from the prospective of the radiographer consultant considering the study objectives, the primary application dissimilarities will be reiterated. With DR, within several seconds of the termination of an exposure, the data will be transformed into an image that appears on the laptop screen. However, if multiple exposures are necessary, for example, a radiographic study of a mounted skeleton, CR will permit as many exposures as necessary. The skeleton of the Centaur at the Barnum Museum in Bridgeport, Connecticut, required 32, 14 × 17 in. (36 × 43 cm) CR image receptors to cover the entire object (Fig. 14). In order to cover the whole skeleton with the X-ray beam, an 18-foot (5.5 m) source-to-image receptor distance (SID) was required necessitating three exposures at 56 kVp and 40 mAs. The 32 images were stitched together using Photoshop™ (Fig. 15). Thus, if obtaining a long enough exposure time is likely to be an issue, CR would be preferred.

However, CR cassettes must be placed in a reader in order to "develop" the image. This necessitates an additional step which increases the examination time. Additionally, if a repeat image is required due to inadequate positioning of the material, the plate has to be repositioned under the object. DR eliminates

Imaging Techniques in Bone Analysis, Fig. 14 An PVC pipe frame (A) was constructed to hold the CR image receptor (B) in each of the 32 positions required to produce a complete radiograph of the Centaur

Imaging Techniques in Bone Analysis, Fig. 15 The 32 CR images stitched together using Photoshop™

both these drawbacks and is thus more suited to rapid throughput.

4. Prior to the onset of the imaging process, it should be decided which material should be included in the study, and the radiographer should determine the number of projections to be taken and the most appropriate imaging methodology. An approximation of "time per case" can then be generated.

   Once that has been determined, a system of workflow should be devised so that the material to be examined can be *queued-up* in anticipation of the radiographic phase of the project.
5. Ideally, there should be a team consisting of a radiographer and assistants (possibly student radiographers or anthropologists) to operate the equipment and position the material/objects in the study. With one individual entering the data into the computer while the other person focuses on positioning, more material can be processed within a short timeframe.

An example of the process, as previously indicated, was the 2015 study in Sicily. A total of 60 mummified priests dating to the early eighteenth and nineteenth centuries were located in the burial crypts of the *Chiesa Madre di Saint Nicolo*. Some were embalmed, while others dried, but all were maintained in an upright position in the basement of the Church. The goal was to examine as many of the mummies as possible in the 3-day period allotted for the project. Since all the remains were in a fragile condition, it was necessary to minimize movement once removed from their respective niches along the wall (Fig. 16).

It was decided that the radiographic component of the study would be optimized by creating two X-ray stations: one for lateral projects, while the other would be solely for anterior-posterior, AP, imaging. Utilizing two stations eliminated not only the need to move the remains to acquire the necessary positioning but also to change the position of the X-ray source from a horizontal to vertical directed X-ray beam. Therefore it contributed to decreasing the time required to complete the examination.

The lateral station was established using a Sedecal SP-HF 4.5 kW output X-ray source and a Cannon Lanmix™ CXDI direct digital radiographic (DR) plate. The unit was set to operate at a focus to film/receptor distance (FFD) of 6 ft (1.8 m) with a kilovoltage of 55 kVp and 5 mAs (Fig. 17a, b). The mummies were placed on a melamine tabletop which was laid directly on the floor. The imaging plate was positioned to the side of the tabletop and the central beam directed

Imaging Techniques in Bone Analysis, Fig. 16 The mummified priests within their niches in the crypt of *Chiesa Madre di Saint Nicolo*

Imaging Techniques in Bone Analysis, Fig. 17 (**a**) The lateral radiograph station consisting of the X-ray source (A), DR plate (B), and the table for the mummy (C). (**b**) One of the authors manipulating the laptop computer to control the lateral station from a safe distance

perpendicular to the plate, thus achieving the horizontal beam lateral projection. Additional support for positioning the mummies was achieved through the use of foam pads as required.

The other station employed a Kubtec 100HF; 3.0 kW output X-ray source was bolted to the base of a bathtub seat (Fig. 18). A 95-in. (241 cm) SID was attained by inserting telescopic tubular poles into each of the legs of the bathtub seat. At that SID, an area of 38 in. (97 cm) was exposed, eliminating the need to move each mummy more than once during each AP imaging session. A mummy table was created using a PVC pipe frame with clear upholstery plastic stretched over the frame. Under the frame, paper covered the floor to protect the Kubtec DIGIVIEW™ 430 DR (Fig. 19). The latter was exposed using 60 kVp at 50 mAs. Three different images were acquired without moving the mummy, therefore providing the opportunity to "stitch" the three images together to produce a single image of a large portion of the mummy.

The team consisted of two senior radiographers, both with experience in forensic and anthropological radiography, and three student radiographers. Students rotated between stations,

Imaging Techniques in Bone Analysis, Fig. 18 The X-ray source support system began with a basic bathtub seat (**a**). With the seat portion removed, the X-ray source was bolted (arrow) into the leg portion of the device (**b**)

but each position always had at least one radiographer and one student. Over the two-and-a-half day period, 245 images were acquired at the AP station, while 326 were obtained at the lateral site (DiCesare et al. 2016).

The images were reviewed by a radiologist and an anthropologist in order to arrive at a diagnosis by consensus (Catapano et al. 2016) and document pathology (Fig. 20a, b). However, aside from the strictly pathologic findings, the advantages available with the digital imaging system need to be considered. The latitude, the ability to demonstrate a wide range of densities, is far superior with a digital image receptor than would be possible with film (Fig. 21). The same image also demonstrated the edge enhancement properties of the algorithm manipulating the data to produce the image. Because it was intended for nonclinical applications, the Kubtec DIGIVIEW™ 430 DR system provides even higher resolution with 100 μm pixels than the Cannon system commonly employed in clinical imaging. The higher-resolution, wider-latitude, edge enhancement properties and the ability to quickly toggle between positive and negative images were clearly seen by the AP images demonstrating the patterns in the priest's vestments (Fig. 22a, b).

Finally, the two stations approach undoubtedly saved a tremendous amount of time and eliminated the need to move the remains more than necessary. However, the importance of capturing two projections could not have been more clearly established by view of the AP projection of the mummy with the wax mask (Fig. 23) and comparing to the lateral view (Fig. 21).

Imaging Techniques in Bone Analysis, Fig. 19 The AP station with the X-ray tube (A) mounted to the legs of the bathtub seat (B). In order to reach the desired SID, telescopic tubular poles (C) were inserted into each of the bathtub seat legs. A mummy table was constructed out of a PVC pipe frame (D) with clear upholstery plastic stretched over the top. Finally, a sheet of paper (E) was placed on the floor under the table frame to protect the DR plate

Imaging Techniques in Bone Analysis, Fig. 20 (**a**) An intertrochanteric fracture of the right femur. (**b**) The fracture was displaced posteriorly

Summary

Radiology has a wide range of applications in the identification and analysis of skeletal remains and associated artifacts and personal effects. It is an invaluable aid in the initial examination of suspected remains and related debris, enabling context to be established and facilitating the rapid identification and retrieval of small skeletal elements and artifacts.

Its applications for human identification and analysis of trauma are especially valuable in situations involving partial decomposed remains or those which have been subjected to fire or fragmented by explosion. From assisting the determination of a biological profile through to determining a positive identification through comparison of antemortem and postmortem images, radiology is an essential tool in the analysis of human remains, and its application and deployment should be readily accessible.

Access to modern cross-sectional radiological techniques such as MDCT and micro-CT scanning is steadily improving as the technology becomes both more economical and widely available. Single-plane radiography techniques have been revolutionized by the availability of digital detectors and developments in battery technology which makes radiography possible in even the most remote and logistically challenging environments, and application of digital technology to "older" techniques such as linear tomography is opening up new possibilities.

Imaging Techniques in Bone Analysis, Fig. 21 Digital image receptors are capable of capturing a wide range of densities from the very dense bone of the skull (A) and the foam sponge supporting the skull (B) to the wax mask covering the face (C). Also note the sharp delineation of the edges of the mask

Greater levels of accuracy and the ability to examine subjects and display images in multiple

Immovable Heritage: Appropriate Approaches to Archaeological Sites and Landscapes

Neville Agnew and Martha Demas
Getty Conservation Institute, Los Angeles, CA, USA

Introduction

Archaeological sites and landscapes exist across the globe at every scale and in every environment, from urban to desolate desert. They include sites with aboveground ruins, ones without visible traces of human occupation or activity, and others that have been occupied and built upon time and again through to the present day with constructions in service to tourism and development. Archaeological sites and landscapes represent the layering of history and transformations of the land by human use, and among all the categories of heritage under threat, they are a resource that is increasingly in jeopardy. Since time immemorial, archaeological sites have been exploited for treasure, looted for objects, destroyed in idle curiosity, and mined to recycle their materials for new construction. So great are the remains of ancient cultures as to seem literally inexhaustible. Not only do we know now that all resources can be depleted but, with population growth, global climate change, and rising sea level, a tipping point may be coming with ultimate consequences that cannot be predicted. Is consumption of the archaeological heritage any different? Our ability in modern times to obliterate what came before us is

formidable and belies the notion of inexhaustible archaeological heritage.

Beyond the spade and trowel approach to revealing buried remains, archaeologists have long realized that understanding the past requires consideration of all physical scales, from the microlevel of pollen analysis to landscapes and regions, and have developed techniques and the necessary interdisciplinary methods to study this continuum. In tandem with this holistic research method, preservation and management of archaeological sites have evolved in a similar and increasingly integrated manner, based on broad considerations of the site in its larger archaeological and natural context, as well as in its contemporary social context of use for tourism, recreation, and education.

Conservation is a catchword in ecology and biodiversity. The concepts and methods of these fields need to be integrated thoroughly with site and landscape preservation, for lost sites, like extinct species, can never be regained, and landscapes, like ecological habitats, are the appropriate scale at which to address preservation. This sturdy belief in the connectedness of the natural and cultural heritage worlds has yet to be fully translated into reality by planners and decision-makers. Increasingly, archaeological sites and landscapes have also come under the purview of urban planners through the realization that they are not isolated, immovable "artifacts," but are a part of the urban fabric and may also be connected with the local community, such as the African Burial Ground National Monument in New York City. The lack of integrated conceptual thinking among various professionals (archaeologists, ecologists, urban planners, conservators) and stakeholder constituencies (cultural descendants, local communities, regional and national governments) remains a distinct challenge in protecting and preserving this heritage.

Definition

An archaeological site exists in a setting, usually a landscape, either natural or created. Considered as a whole, an archaeological site and its landscape comprise a repository of information about activities of people over time and their effect on the natural environment. Physical scales vary, and either site or landscape may dominate. On the one hand, the site and landscape may be of the same scale, as, for example, at Angkor in Cambodia; on the other, the site may be a rock overhang with painting in an extensive natural landscape, as is the case for rock art sites throughout the world (Fig. 1). From a preservation perspective, it is important to regard both as one. Site and landscape have relational values – topographic and geomorphological features, ecological attributes, archaeological resources, and research potential.

Immovable Heritage: Appropriate Approaches to Archaeological Sites and Landscapes, Fig. 1 Traditional owners guiding visitors to rock art sites in the tableland above the floodplain at Gunbalanya, Arnhem Land, N.T., Australia, help ensure a sustainable future for the sites and community. (Photo: 2012, J. Paul Getty Trust)

It is the role of the archaeologist to define the extent of both site and landscape. The field of landscape archaeology is premised on landscape being important to archaeology's goal (Anschuetz et al. 2001). Archaeological sites and landscapes may themselves be considered a subset of cultural landscapes (Fowler 2003).

Historical Background

Threats to archaeological sites and landscapes in the contemporary world come from many sources, and the approaches to preserving them have become commensurately complex and wide-ranging. In the 1970s, mainly in response to the destruction of archaeological resources from uncontrolled development pressures, there began to emerge a philosophy of conservation, referred to as the "conservation ethic," first put forward by William Lipe (1974). The approach heralded a paradigm shift in the conduct of archaeological research, in which a conservation model was advocated to replace the "exploitative model," based on excavation that had guided the practice and theory of archaeology and was now seen as a contributor to the loss of archaeological heritage.

The conservation ethic argued for the use of nondestructive techniques of investigation over excavation of sites. When excavation does take place, it advocated that priority should be given to sites that are threatened, research-based excavation be limited to the minimum necessary to answer research questions, and excavation proceed slowly, with time and staff devoted to specialist's studies and retrieval techniques that enhance the quantity and quality of information. These practices have become fairly standard in archaeology. They can be seen in the growth of contract archaeology in the 1970s and 1980s, spurred on by the passage of legislation requiring impact assessments prior to development, and they are evident in the use of tools such as GIS (geographic information systems) and various remote sensing techniques such as aerial photogrammetry, laser scanning, satellite imagery, and multi- and hyper-spectral data collection (Cowley and Sigurðardóttir 2010). Research excavation has been curtailed in many parts of the world, with a much greater emphasis on conservation of the resource. Along with more limited excavation, there has also come stricter enforcement of mandatory conservation and publication by the archaeologist who seeks to excavate. Against this backdrop arose the allied field of archaeological heritage management (or cultural resource management), whose precepts are reflected in the *ICOMOS Charter for the Protection and Management of the Archaeological Heritage* (1990).

Key Issues/Current Debates

Values of the Archaeological Heritage

Values are the raison d'être for conservation. Archaeological sites and landscapes in all their diversity have multiple values. These values have been enumerated by many authors who stress authenticity and integrity as essential attributes when discussing conservation and management (e.g., Lipe 2009). It is acknowledged that values are ascribed by society and thus may be expected to differ between cultures; they are not immutable and may shift in response to societal changes. In contemporary thinking, social values broadly writ (associative, symbolic, educational, spiritual) have come to take precedence as societal use of sites (and the economic benefits derived from using them) have become a form of legitimization and justification for preservation and as the claims of descendant communities for a stake in their ancestral places have been voiced.

For archaeologists, historians, and scholars whose professional lives depend on archaeological sites, historical and artistic values have been enduring core values. More than other categories of cultural heritage, archaeological sites are repositories of information and artistic creation essential to understanding and interpreting the past. For this reason alone, historical and artistic values, which have been central to informing conservation decisions in the past, will continue to be of fundamental importance to guide decision-making.

Also of fundamental importance is research value. This is the potential of a site to yield new

information and answer research questions. Research value is often not considered adequately when making decisions about the future of a site or landscape. There is a tendency to plan for and manage sites based on their revealed or known values, but it is equally important for many types of archaeological sites to be protected and managed for their future potential to yield information. Among these, for example, are wetland sites which may preserve organic remains and archaeological landscapes such as battlefields and cemeteries. Sites with high research potential often need protection against looting, poor excavation strategies, erosion, agricultural activity, and so forth, or need prioritization for excavation if threatened.

The visual values of an archaeological landscape may be among its most important attributes (Fig. 2). The past tendency to focus on the site to the exclusion of its setting has changed in recent times and the 3-dimensional nature of the landscape, its topographic features, scenery, and ecology, now receives more attention. This includes the sky, as, for example, at Chaco Culture National Historical Park, where the night sky is interpreted by staff and volunteers as an aesthetic and educational value for city dwellers and the young, some of whom may never have seen a night sky without light pollution.

Conservation and Management of the Archaeological Heritage

The practice of archaeology with a conservation ethic contributed significantly to protecting and preserving archaeological sites and landscapes, but cannot address the full spectrum or magnitude of threats. War and its frequent fellow-traveler looting, and natural threats from fire, flood, tsunami, and earthquakes, being immediate, can devastate sites, while the slower processes of pollution, weathering, and erosion take their toll (Fig. 3). To these threats may be added the effects of climate change, which are certain to be severe. Contributing to deterioration has been the post-excavation neglect of sites, especially in parts of the world where archaeological sites have extensive architectural remains, such as the Mediterranean, Near East, Central Asia, China, the southwestern United States, Mexico, and Central America. With few exceptions, only those sites with proven touristic potential have been provided with a modicum of maintenance and protection. These sites are a minority and they are not immune from causes of deterioration and from the unintended consequences of mass tourism.

Conservation science and technology and increasingly sophisticated methods of site stabilization and treatment have made real strides in

recent decades, but are sometimes seen as the panacea that will save for the future what is precious and valued today, if only the resources could be mustered to undertake the necessary conservation programs. The sad truth is different however – all cultural resources deteriorate no matter what is done. The best that can be hoped for is that rates of loss can be slowed by preventive measures, by wise use, by appropriate interventions and custodianship, and by prioritization for protection and treatment. Regional surveys are the most fruitful approach to assess risk and establish priorities for protection and conservation, as, for example, in the survey of megalithic art in the Galicia region of Spain (Carrera Ramírez and Fábregas Valcarce 2003). True integration of conservation into the research and excavation plan at the outset remains a goal to be achieved, but notable exceptions, exemplified at the site of Tell Mozan/Urkesh in Syria (Buccellati 2006), demonstrate the benefits for archaeology, the site, and the local community (Fig. 4).

Management of archaeological sites is essential to long-term care and sustainable use of sites. Like science in the service of conservation, management is a tool for preservation. Underlying the management approach is a reductionist process. It is powerful because it allows one to understand how things work – as it does in scientific investigation. From the reductionist analysis is derived the management plan. It determines the values; examines the significance to various interest groups and constituencies (including the obligation to future generations); assesses threat and risk; determines causes of deterioration and their rates wherever possible and derives a prognosis; develops a conservation strategy (which may include development for display or education; or reburial); considers constraints and side effects of proposed technical interventions; communicates the written plan to stakeholders; and implements the program, with assurance that documentation, management, future monitoring, and maintenance have been secured. Also, it should not be

Immovable Heritage: Appropriate Approaches to Archaeological Sites and Landscapes, Fig. 4 The site of Tell Mozan/Urkesh in northern Syria, with its mudbrick walls protected and interpreted by fitted tarpaulin covers, exemplifies excavation working hand in hand with conservation. (Photo: 2006, IIMAS – The International Institute for Mesopotamian Area Studies)

forgotten that when sites are lost or damaged, the final line of defense should be the survival of their documentary record. Each of the elements in the analysis requires its own specialized field of expertise. Essentially, the preservation and management of sites require a vision that is encompassing and holistic (Demas 2002). Various charters have sought to promote this; the *Burra Charter* (the *Australia ICOMOS Charter for Places of Cultural Significance*) may be mentioned as one of the most effective.

The interface between a site and its management with stakeholders and traditional owners, both local and more broadly defined as the "public," is often crucial to sustainability of desired outcomes (see, e.g., Fig. 1). Numerous examples have shown how understanding the "social landscape" of a place is as important as its archaeological and natural landscape (Egloff 2006), but stakeholder relations may also be fraught when, as is frequently the case, conflicting interests bear upon access, use, benefit, and so on. Patient negotiation, understanding of different objectives, and time are needed for satisfactory resolution, as in the cases of the Côa Valley Archaeological Park, Portugal (Batarda Fernandes et al. 2008), and the "flagship" monument of Stonehenge, which endured many years of planned improvements without resolution (Baxter and Chippindale 2002). The unwise assumption of officials, on the other hand, that local communities are irrelevant has led to vandalism of one of the most important heritage sites in Zimbabwe (Taruvinga and Ndoro 2003).

Monitoring and maintenance of an archaeological site and its landscape are fundamental management responsibilities. Maintenance is a routine activity, whose absence constitutes one of the greatest and least recognized threats to long-term preservation. Analysis of the failure of maintenance at the large site of Herculaneum and the structured public/private partnership designed to meet the conservation and management challenges exemplifies the problem (Thompson 2007).

Monitoring is not an end in itself. Its purpose is to provide information on the condition of the heritage place, or the quality of the visitor experience, or effectiveness of management itself, in order that certain necessary actions should follow. Yet, systematic monitoring does not have a good track record. Why should this be so? More to the point: what explicit link in the design of monitoring is made between monitoring as an activity and the follow-through to redress a threat or to halt continuing damage? How often do monitoring reports end up on the shelf because no

mechanisms or management policies have been established to act upon the findings and recommendations?

This point is not trivial when one thinks about the sequence: monitoring data and information require processing and assessment, followed by a decision as to what action should be taken; next is the identification and garnering of resources (human and financial) to act upon the decision, followed by implementation to reverse or halt the situation. The process is then repeated with a new cycle of monitoring. Too often there is a break in the chain and the only result is inaction. Monitoring programs need to be conceived integrally and coupled directly with mechanisms for implementation. This is a perceptual and management problem. With the many threats to cultural and natural heritage areas becoming more acute, it is no longer good enough to think of monitoring as an "exercise" – it is a vital need. Natural areas have been generally more effectively monitored than cultural ones, ultimately as a result of greater awareness and support from the profession and the community at large. Monitoring must progress from reactive to proactive mode – it cannot continue to remain the orphan of heritage management (UNESCO World Heritage Centre and ICCROM 2004). At the scale of the landscape, satellite imagery and GIS (Fig. 5) have become essential planning and monitoring tools (Hernandez 2004).

Buffer zones as protection for heritage sites are important where encroachment, development, and competing land use are threats. A buffer zone is

Immovable Heritage: Appropriate Approaches to Archaeological Sites and Landscapes, Fig. 5 The MEGA-Jordan web user interface, utilizing open source software and Google Earth satellite images, displays a site's recorded boundary and site elements and data for site planning and monitoring. (Photo: 2012, J. Paul Getty Trust)

required for World Heritage list inscription, though it is not a formal component of the property. A buffer zone should be larger, but is often smaller, than the known extent of an archaeological site. Under the best circumstances, the zone may enhance the site and landscape and protect its visual catchment and function as a refuge for the natural environment and ecological diversity. Nonetheless, a number of important constraints have emerged in the application of buffer zones that reveal complexities of what is a seemingly straightforward concept. These may be inaccessibility to the site of surrounding community engendering a sense of exclusion, not participation, leading to alienation and hostility; management by different jurisdictions under different sets of regulations; resentment when competition for land use is strong; and poor understanding at the local level of the buffer zone's purpose. The term itself is not apposite, implying a reactive attitude to buffeting by extraneous forces ranged against those of preservation. These matters have been well dealt with in a number of studies of the operational constraints of buffer zones (Foster and Linge 2002; Martin and Piatti 2009).

Impact of Urban and Rural Development on the Archaeological Heritage

Urban development and rural development have had enormous consequences for archaeological sites and landscapes in the post-WWII period. This era of large-scale development impacts on archaeological sites and landscapes began with the Aswan High Dam and the UNESCO led international mission to rescue the Abu Simbel temple. This level of international cooperation has never been repeated. Along with population growth, tourism and its requisite infrastructure, rising sea level, and greater competition for water and arable land are all likely to lead to greater impacts on sites. Consequently, construction of water storage and distribution engineering works are to be expected in an attempt to meet economic growth. The impacts on sites and landscapes will be immense. Already we have seen the effects on sites and monuments of the Three Gorges Dam on the Yangtze River (Wang 2008) and the Zeugma dam project on the Euphrates in Turkey (Kennedy 1998). In Western Australia, the extensive petroglyph landscape on the Burrup Peninsula has been the subject of protracted and bitter struggle between preservationists and developers (Bednarik 2006).

Among key issues facing decision-makers are large-scale archaeological sites in heavily populated urban areas. Sites of great significance across the broad sweep of China's long history, such as Neolithic Liangzhu in Zhejiang province and the Qin, Han, and Tang dynastic remains in Xi'an (Fig. 6), pose challenges because of their great extent and the social and socioeconomic

Immovable Heritage: Appropriate Approaches to Archaeological Sites and Landscapes, Fig. 6 Daming Palace Archaeological Park in Xi'an, Shaanxi Province, in its urban context. Residents and factories were relocated to allow development and interpretation of the site. (Photo: 2012, J. Paul Getty Trust)

impacts of conserving them. Moreover, the absence of visible aboveground remains means that when excavated and protected, a new landscape requiring interpretation is created. Liangzhu, in the Yangtze River basin within the municipal area of modern-day Hangzhou, with remains dating from 3000 to 2000 BCE, is important for study of the late Neolithic period and the development of Chinese culture. Heavily populated, in a country undergoing rapid development and urbanization, the site, covering an area of 60 km^2, is threatened by construction, earth moving, and other large-scale development works. Balancing the needs of the inhabitants with protection will result in constraints on activities, including industry and agriculture and some relocation of population to newly planned townships. Local inhabitants are reportedly ambivalent about preservation of the site, hoping, but skeptical, on the one hand for benefits from tourism but fearful about restrictions on their way of life and relocation (Chen 2006). In the case of Xi'an, efforts to preserve parts of the immense ancient landscape include incorporating significant elements into the urban fabric, returning land to use for farming after trial excavations, and demarcating parts of protected sites for nonintrusive public recreation by local residents, many of whom were displaced to create a protected zone.

In recent years, a consortium of professionals has begun to look for viable models for preserving threatened urban sites in situ rather than resorting to salvage archaeology. Like so many currents today, this initiative involves expertise from a wide range of subject areas and a concerted effort to establish a research framework within which questions can be answered, and while starting in a European context, it has become increasingly more international in scope (Kars and van Heeringen 2008).

Impacts of Tourism on the Archaeological Heritage

To the twin threats of construction and human development pressures, mass tourism may be added to the devastation matrix for the archaeological heritage. Tourism in its various guises is one of the largest industries in the world. Tourism to archaeological sites, notably those with World Heritage status, has burgeoned, while shifting from one region to another during crises, whether from political unrest or epidemics. When stability returns, tourist numbers rapidly rebound. The impact of mass tourism on sensitive sites and their surrounds degrades the cultural resource and the visitor experience. Iconic sites bear the brunt of the relentless flow of often one-time visitors: one thinks of Machu Picchu, Stonehenge, Angkor, and the Valley of the Kings (Fig. 7). The

Immovable Heritage: Appropriate Approaches to Archaeological Sites and Landscapes, Fig. 7 Visitors to the Valley of the Kings on the West Bank of Luxor preparing to take electric vehicles from the visitor center to the tombs in the distance. (Photo: 2003, J. Paul Getty Trust)

multiple impacts of tourism on the site of Angkor and its environs have been intensively studied. Among the many problems resulting from the great increase in tourism over the past 10–15 years have been developments that service international tourists, pollution, sociocultural deterioration resulting from benefits not accruing to local population, and rising land prices that force people out. The economic benefit cycle is largely in favor of foreign and local business elites. This situation equates to exploitation of the site and of the local inhabitants. There are some positive developments, however: traditional crafts promotion, organic farming, and forest regeneration, but these may be too little, too late to counter the influences of development and mass tourism (Miura 2007).

Egypt exemplifies the forces of uncontrolled development, population pressures, mass tourism, and poverty on iconic archaeological landscapes. Encroachment and population pressure at the Giza plateau, as visitors to the pyramids can attest, has overwhelmed the setting to the extent that Egypt's national authority, the Supreme Council of Antiquities, has constructed a wall to limit further advances. At Qurna, on the West Bank at Luxor, the situation is somewhat different. Here the Qurnawis have lived above the Tombs of the Nobles for generations and were famed as tomb robbers, which may have been true in the late nineteenth and early twentieth centuries, but this can scarcely be said of them today. Instead, they now provide skills and labor to archaeologists and the SCA and offer trinkets to tourists. For decades they have successfully resisted efforts to be moved from the site. Periodic attempts to move them have led to bloodshed and deaths until recently when through temptation (new housing located to the north) and coercion (demolition of their houses), the population has been mostly moved leaving a few mudbrick structures on the hillside to provide a visual backdrop for tourists on the way to the Valleys of the Queens and Kings (Fig. 8). The connection between community and culture has been broken here, and the livelihood of a traditional community that lived in proximity to and in context with the ancient archaeological landscape has been greatly diminished (van der Spek 2011). What remains is rubble on a bulldozed hillside.

Tourism is a juggernaut fueled by the forces of economic growth and often is justified as a means of poverty alleviation by development agencies, without due consideration for the negative impacts on local communities and archaeological sites, especially in contexts where regional planning and coordination among agencies are inadequate to nonexistent. Ranged against these forces are national and local preservation authorities who generally have inadequate power to balance the

Immovable Heritage: Appropriate Approaches to Archaeological Sites and Landscapes, Fig. 8 Theban mountain and archaeological landscape of the West Bank of Luxor, showing the Valley of the Queens and Deir el-Medina in the center of the image and some of the Qurna village houses below. (Photo: 2007, J. Paul Getty Trust)

scales. Guidelines and tools to limit visitor capacity exist but are often not applied or cannot be validated by adequate study and scientific data to show the degradation to the site and its setting. Better methodologies and flexible policies need to be developed, building on concepts such as the limits of acceptable change developed for natural sites (McCool and Cole 1998). Natural sites can regenerate when allowed to by closure of damaged parts; but cultural resources such as archaeological remains cannot do so – all damage is irreversible and cumulative. Restoration of damage at archaeological sites is a poor substitute for preservation of the original, and over time, with repeated repairs, the sites' authenticity is inevitably degraded.

International Perspectives

Countries may differ markedly in the particular threats to their heritage and in the approaches to protection and preservation. Countries struggling under the burden of poverty are severely hampered by inadequate budgets and with few trained, motivated professionals cannot cope well with the demands of cultural resource management. Many such countries are rich in archaeological heritage. It behooves wealthier countries to provide assistance, and many do, through UNESCO and various national and private programs and aid agencies and development banks. Some successful models exist, but often these are focused on high-visibility sites with less emphasis on prosaic, intangible though essential needs such as inventory, documentation, and training. Ultimately, however, it is the national authority that must provide direction and coordination and establish priorities and policies within which agencies and individuals can work toward a common purpose.

Despite a number of shortcomings in protecting its archaeological heritage, China has shown some ways forward. It has an exemplary national inventory process that continuously identifies and records sites; an ambitious program of surveying, documenting, and nominating for World Heritage listing sites, landscapes, and monuments on a regional scale, such as the ancient Silk Road, the Great Wall, and the Grand Canal; and a national policy to prioritize salvage excavation and a research and planning strategy to deal with its so-called big-scale archaeological sites, such as Xi'an and Liangzhu as part of state-level 5-year planning. There are fault lines in these strategies but they constitute a pragmatic attempt to deal with big-scale problems employing nationally constructed solutions that seek to balance the strong desire to preserve their past and the needs of contemporary society to develop. What has not yet been tackled in any meaningful way is mass tourism, reaching crisis levels at some archaeological sites and created in part by a national policy that identified tourism as a pillar industry (Sofield and Li 2011).

Although the example of China presents a different context and utilizes different strategies, it has parallels with efforts undertaken in the United States in response to destruction of archaeological sites due to development. In the USA, passage of the National Environmental Policy Act (1969) requiring impact assessments and public input to the process, growth of private contract archaeology services, restriction on excavation by public agencies, development of cultural resource management policies, and theoretical developments within the academy, all emerged in the decades of the 1960s and 1970s. The US model is an eclectic mix of national and private efforts, whereas China is a top-down approach, but both aim to address large-scale problems and establish priorities for protecting sites.

Egypt exemplifies an archaeological heritage at the mercy of unsustainable development, human population pressures, poverty, and mass tourism, coupled with weaknesses in civil institutions, which has forced the national and site authorities into a reactive position. Archaeologists have long been part of the problem, driven by their narrow, individual objectives, but they have begun to become part of the solution, willingly or not, as they take on conservation responsibility for their excavations, find alternatives to large-scale excavation, and rally to the defense of local populations and preservation of the resource beyond their archaeological "concessions." While individual missions and archaeological

schools can achieve considerable results when working in a coordinated fashion, it is clear that research, planning, and policy development on the one hand and interagency cooperation on the other are required at the regional and national level to address the many challenges at hand.

Future Directions

As the threats to the archaeological heritage become more complex, interconnected, and larger than any one profession can handle, so too must the responses be equal to the task. It is clear that more holistic thinking and integrated regional and urban planning and working across disciplines in unfamiliar territory are where the future lies. National surveys to identify, document, inventory the resource, and establish priorities for salvage and research excavation are still sorely lacking in a field accustomed to setting its own research priorities based on very different criteria of the academy.

Appropriate approaches need to address the greatest threats. Globally archaeological sites are being lost to development on an unprecedented level. In the absence of systematic inventory in many countries with a rich heritage, sites may simply disappear without record or trace. Prosaic matters of inventory, investigation, documentation, monitoring, and maintenance are low on the priority list in many countries. Archaeology would be well served by seeking out broader partnerships to bring to bear the new technological tools for recording and to engage with environmentalists, ecologists, tourism, and wider stakeholder bases in the management and wise use of sites.

Imperative Military Necessity: Hague Convention (1954) and Its Protocols

Agostina Noelia Cichero
Law, University of Buenos Aires, Province of Buenos Aires, Argentina

Introduction

The Law of Armed Conflict (LOAC), also known as International Humanitarian Law (IHL), is a branch of international law that seeks to limit the effects of armed conflicts for humanitarian reasons. IHL protects persons who are not or no longer participating in hostilities and restricts the means and methods of warfare. Therefore, under the LOAC, the right of belligerents to adopt means of injuring the enemy during an armed conflict is limited. In this sense, IHL is a compromise based on a balance between the requirements of humanity and the principle of military necessity (Pictet 1987). The LOAC allows belligerents a certain liberty in keeping with the demands of military necessity, which is also limited by considerations of humanity (Dinstein 2004).

Cultural property is protected in the event of armed conflict under IHL, by treaty and customary law. The 1954 Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict (1954 Hague Convention) (see Schipper's entry ▶ "Convention for the Protection of Cultural Property in the Event of Armed Conflict (1954)") establishes that States have a duty to respect cultural property and to refrain from using such property and its surroundings in any way that may expose it to destruction or damage and from any act of hostility. This duty has only one exception: States may waive the prohibition in cases where "imperative military necessity" requires it. Furthermore, Chap. II of the 1954 Hague Convention establishes a special regime of protection for a limited number of cases. Cultural property placed under special protection has immunity, as stated by Article 9 of the convention. In order to lift such immunity, the convention establishes a higher standard of military necessity, called "unavoidable military necessity."

Definition

Military necessity is a paramount notion when it comes to the protection of cultural property; however, the 1954 Hague Convention and its Protocols are not clear about what this means or what the difference is between the different standards of military necessity it contains. Article 6 of the 1999 Second Protocol to the 1954 Hague Convention (Second Protocol) sheds some light on its meaning by stating that imperative military necessity may only be invoked when there is "no feasible alternative available to obtain a similar military advantage to that offered by directing an act of hostility against that objective." Furthermore, Article 6 requires that the property in question has, by its function, been made into a military objective. According to Article 42 of Additional Protocol I to the 1949 Geneva Conventions and relating to the protection of victims of international armed conflicts, "[i]n so far as objects are concerned, military objectives are limited to those objects which by their nature, location, purpose or use make an effective contribution to military action and whose total or partial destruction, capture or neutralization, in the circumstances ruling at the time, offers a definite military advantage." Article 6 of the Second Protocol to the 1954 Hague Convention also requires that the decision to attack cultural property be taken by a certain level within the chain of command, as well as an effective warning, whenever circumstances permit.

Historical Background

The idea of necessity as an exculpatory ground in the context of armed conflict can be traced back to antiquity. For instance, Thucydides describes that the Athenians justified occupying a temple and removing water from its sacred well as reference to the necessities of war. In one of its passages, the author explains that the Athenians considered they had done no wrong since "for the water, they meddled with it upon necessity (...) for whatsoever is forced by war or danger hath in reason a kind of pardon even with the god himself; for the altars, in cases of involuntary offences, are a refuge, and they are said to violate laws that are evil without constraint, not they that are a little bold upon occasion of distress" (*History of the Peloponnesian War* 4.98).

The notion of military necessity can also be traced back to the nineteenth-century German doctrine of *Kriegsräson*, so-called in virtue of the maxim *KriegsräsongehtvorKriegsmanier* (the necessities of war take precedence over the laws of war). *Kriegsräson* is previous to the codification of IHL, which means it belongs to a time when armed conflicts were regulated by simple uses alone, not by the laws and customs of war (Dunbar 1952). This doctrine was utterly rejected in the trials conducted under the Control Council law No. 10 after Nuremberg.

In 1864, Francis Lieber, a German lawyer who fought for Prussia in the Napoleonic Wars and in the American War of Independence, wrote by request of then President Abraham Lincoln the "Instructions for the Government of Armies of the United States in the Field, General Order № 100." The instructions, commonly known as the "Lieber Code," were the first attempt to codify the laws and customs of war. Articles 34 and 35 of the Code refer to military necessity as "the necessity of those measures which are indispensable for securing the ends of the war, and which are lawful according to the modern law and usages of war."

In 1907, during the Second International Peace Conference, States adopted the IV Convention respecting the Laws and Customs of War on Land, and its annex, the 1907 Hague Regulations. According to Article 23(g) of the 1907 Hague Regulations, it is prohibited "to destroy or seize the enemy's property, unless such destruction or seizure be imperatively demanded by the necessities of war." Military necessity was often used as a justification for the extensive destruction of cultural property perpetrated during World War I (Forrest 2010).

As a response to the events of World War II, which was marked by the massive and indiscriminate bombardment of both civil and military objectives, as well as acts of pillage and illegal export of movable cultural property, States adopted the 1954 Hague Convention, which in Article 4(2) includes the exception of military necessity. Furthermore, after World War II, the Allied Control Council issued in 1945 Control Council Law No. 10, which allowed the occupying powers to try alleged war criminals in their occupation zones. These trials were commonly known as the "subsequent Nuremberg trials," since they took place after the trials held by the International Military Tribunal at Nuremberg (IMTN). In the case known as the "hostages trial" (United States v. Wilhelm List et al. 1949a), the US Nuremberg Military Tribunal held in 1948 that "military necessity permits a belligerent, subject to the laws of war, to apply any amount and kind of force to compel the complete submission of the enemy with the least possible expenditure of time, life and money." In the 1980s and 1990s, the events of the war in Iraq and Kuwait showed there were many problems regarding the implementation of the 1954 Hague Convention. Thus, in the 26th session of the UNESCO General Conference, after noting that the existing international system for the protection of cultural property was not entirely satisfactory, the UNESCO created a group to study the possibility of amending the Convention or complementing it by means of a Second Protocol. The group was directed by Prof. Patrick Boylan, who in its 1993 report concluded that, in case of an amendment, the notion of military necessity should be eliminated (Boylan 1993). This opinion was shared by many States, who considered that the exception weakened the protection of cultural property in the event of armed conflict (O'Keefe 2004). In 1999, the Second Protocol to the 1954 Hague Convention was

adopted. Although the notion of military necessity was not eliminated, attempts were made to further specify the meaning of this exception and reduce ambiguities. Neither the 1954 Hague Convention nor the Protocols explain what the difference between imperative and unavoidable military necessity is. Furthermore, the whole body of LOAC is filled with different standards of military necessity with no reference to their meaning. For instance, Article 54 of the 1907 Hague Regulations Concerning the Laws and Customs of War on Land (1907 Hague Regulations) refers to "absolute" necessity, and Articles 33 and 34 of the 1949 I Geneva Convention on Wounded and Sick in Armed Forces in the Field mention "urgent" military necessity. Whereas some authors consider that the different standards simply emphasize the severity of the necessity contemplated (McCoubrey 1991), others consider that these qualifications should be ignored for being redundant (Dinstein 2010).

Military necessity was originally coined as an exception to certain specific IHL rules, operating on a state-to-state basis. However, it can also operate as an exception under international criminal law (i.e., the branch of international law that deals with the responsibility of individuals for the commission of international crimes) to justify a conduct which would otherwise be criminal. Indeed, the Statute of the IMTN and the International Military Tribunal for the Far East (IMTE) provide that war crimes include "plunder of public or private property, wanton destruction of cities, towns or villages, or devastation not justified by military necessity." Similarly, Article 2(d) and 3(b) of the Statute of the International Criminal Tribunal for the Former Yugoslavia (ICTY) consider a war crime the "extensive destruction and appropriation of property, not justified by military necessity and carried out unlawfully and wantonly." Finally, the Statute of the International Criminal Court (ICC) established as a war crime the "extensive destruction and appropriation of property, not justified by military necessity and carried out unlawfully and wantonly" (Art. 8.2.a.iv), "destroying or seizing the enemy's property unless such destruction or seizure be imperatively demanded by the necessities of war" (Art. 8.2.b.xiii), and "destroying or seizing the property of an adversary unless such destruction or seizure be imperatively demanded by the necessities of the conflict" (Art. 8.2.e.xii).

Key Issues/Current Debates

The notion of military necessity has served several purposes and has been interpreted in different ways throughout history. According to the theory of *Kriegsräson*, "any given military action that is in fact materially necessary for the successful prosecution of war overrides and renders inoperative any provisions of the laws and customs of war that prescribe contrary action" (Hayashi 2010). In the German High Command Trial, the US Military Tribunal held that if military necessity conferred a belligerent the right to do anything which contributes to win the war, "such a view would eliminate all humanity and decency and all law from the conduct of war and it is a contention which this Tribunal repudiates as contrary to the accepted usages of civilized nations." At present, this theory is widely discredited.

According to a different current, IHL violations are justified only when the very survival of the State is at stake. This theory was rejected by the US Military Tribunal in the Krupp case, in 1948, where the Tribunal affirmed that the "rules and customs of warfare are designed specifically for all phases of war. They comprise the law for such emergency. To claim that they can be wantonly –and at the sole discretion of anyone belligerent– disregarded when he considers his own situation to be critical means nothing more or less than to abrogate the laws and customs of war entirely." Those who sustain this theory note the advisory opinion delivered by the International Court of Justice on the legality of the threat or use of nuclear weapons, where the Court stated that it could not "conclude definitively whether the threat or use of nuclear weapons would be lawful or unlawful in an extreme circumstance of self-defense, in which the very survival of a State would be at stake." However, other authors consider that this interpretation of the Court's decision is actually inaccurate, since the Court was not referring in this paragraph to the notion of military necessity or the violation of IHL

norms, but to the violation of the prohibition of the use of force and the exception of self-defense (Dinstein 2010).

A third stream considers that military necessity operates as the measure of what is legal or permitted; it is in these terms that the Lieber Code is expressed. As a consequence, only those acts which are necessary to the attainment of a military goal would be permitted, therefore excluding acts which do not qualify as a "necessity," such as cruel acts, revenge, mere convenience, etc. Just like the doctrine of *Kriegsräson*, this theory is previous to the systematization and establishment of recognized rules of IHL, which is why, in that context, military necessity did not work as a habilitating institute but, quite to the contrary, it had a limiting effect (Dunbar 1952).

Finally, most scholars (Pictet 1987; Dunbar 1952; Dinstein 2004; Hayashi 2010) consider that military necessity has a double function: on the one side, it is a principle underlying the whole body of IHL; on the other side, it works as an exception when the norm which prohibits a certain conduct expressly provides for its derogation in cases of military necessity. Both functions are intrinsically connected. In effect, IHL rules are the result of the tension between the principles of humanity and military necessity. Since every norm already accounts for military necessity, de novo invocations – that is, invocation in cases where military necessity is not expressly included as an exception to the protective rule – are strictly prohibited. Therefore, the exception of military necessity must be expressly included in the norm.

The idea of necessity as a justifying notion does not appear exclusively in IHL, but in several areas of international law as well. For instance, the International Law Commission's articles on responsibility of States for internationally wrongful acts consider state of necessity as one of the circumstances precluding the wrongfulness of an act. There are many similarities between the two notions, which may sometimes lead to confusion. However, state of necessity is a circumstance precluding wrongfulness (in other words, a secondary norm), whereas military necessity is an exception that operates within the primary norm which determines the prohibition of a certain conduct, so that there is no actual violation. State of necessity precludes the wrongfulness of a conduct although the violation of an international obligation persists (in fact, the violation of an international obligation is a constitutive element of the notion of necessity), whereas military necessity determines that there is no violation of the primary norm.

International Perspectives

Military necessity is a foundational notion of IHL. Particularly regarding the protection of cultural property in the event of armed conflict, it marks the limit of what is permitted and what is prohibited. In this sense, its relevance is associated with traditional conflicts between States, or international armed conflicts, by acting as an exception to the protective rule and, therefore, in the absence of a violation to an international obligation, by excluding the international responsibility of States. However, it is also relevant in the context of non-international armed conflicts, where non-State armed groups are a party to the conflict, since absence of military necessity usually constitutes one of the elements of the war crime of wanton destruction of cultural property.

Future Directions

Given the ambiguity of the notion, military necessity has been invoked to justify any measure. The rejected doctrine of *Kriegsräson* is an extreme example of the manipulation this notion can be subject to. For this reason, it has been severely criticized by human rights defenders, NGOs, and some States. However, a certain degree of ambiguity is unavoidable. Indeed, military necessity is an open norm, designed to rule in those situations which cannot be foreseen. Thus, its very nature makes it impossible to give a complete and all-encompassing definition of these notions.

In this context, a possible approach could be to focus on the case-law of international and domestic tribunals, as guidelines to identify the elements that constitute the notion of military necessity. In

this sense, some of the requirements that different tribunals have identified are that the measure (the act affecting cultural property) must be taken for a specific military purpose; that the measure must be materially relevant to the attainment of such purpose; that of those materially relevant measures that were reasonably available, the measure taken was the least injurious; that the injury that the measure would cause must not be disproportionate to the gain that it would achieve; that the military purpose for which the measure was taken was in conformity with the International Humanitarian Law; and that the measure was otherwise in conformity with IHL (Hayashi 2010).

Imperial Cult, Roman

Candace Weddle Livingston
South Carolina School of the Arts at Anderson University, Anderson, SC, USA

Introduction

Although there was a strong and ancient tradition in Roman culture of honoring the spirits of the dead (*Manes*), prior to the third century BCE, the Romans did not deify mortals. They did honor the *Genius* of a living man (just so, the *Juno* of a woman); these terms, however, denoted a divine force present in every human but at the same time distinct from him, and their worship should therefore not be considered equivalent to the worship of deified humans. The actual deification of individuals only came into practice following contact with Hellenistic cultures as the empire expanded; the concept of worshiping the emperor as a deity seems generally to have been an outgrowth of the Greek practice of deifying heroes and Hellenistic kings. The development of those earlier cults of heroes and kings, as well as later divine honors offered to prominent Romans, has been seen by modern scholars as adaptation by the Greeks of the cults of their traditional Olympian gods in order to express their relationship to new types of power.

Definition

The terminology "imperial cult" is used by modern scholars to refer to the practice in the Roman Empire of worshiping the emperor and certain members of the imperial family. There was no cult designated by that name in antiquity. Nevertheless, worship of the emperor, which began with the deification of Augustus in 14 CE and continued throughout the imperial period, was an important aspect of the religious and political life of the empire, and it is convenient to assign it a name in order to facilitate discussion.

Historical Background

The first Romans for whom we have evidence of divine honors were M. Claudius Marcellus, for whom a festival was established in Syracuse, Sicily (212 BCE), and, in the East, the consul Titus Quinctius Flamininus (ca. 191 BCE), on whom honors were bestowed in Greece. Importantly, although the Greeks occasionally offered temples in addition to divine honors to Roman dignitaries and officials (Cicero (106–43 BCE), e.g., refused such an offer), there is no evidence that any were actually built. The Senate voted a cult and a *flamen* (that is, a priest – in this case, Marcus Antonius) for C. Julius Caesar (100–44 BCE) a short time before his assassination, and Caesar was officially deified after death; those divine honors served as models of appropriate behavior toward the emperors throughout the imperial period. Augustus (r. 27 BCE–CE 14) was offered divine honors from the eastern provinces of Asia and Bithynia while living, which he accepted with the stipulation that the cult include Roma as a partner goddess, a precedent that was followed by several of his successors. Augustus refused deification in Rome itself during his lifetime but permitted the establishment of a cult of the *Genius Augusti* by 12 BCE (see esp. Taylor 1975). Following his death in 14 CE, Augustus received honors similar to those bestowed on Julius Caesar, including a temple, a *flamen*, and the establishment of a college of priests for his cult, the *Sodales Augustales*, whose members were drawn from the ranks of the Senate.

Technically speaking, the emperor could only become a god (*divus*) and be the recipient of an official cult after death, following an apotheosis as declared by a decree of the Senate (note, however,

that *divus/divi* is still distinct from *deus/dei*, the term for the traditional gods). In practice, this rule was only ever observed in Rome and some of the western provinces (see below). In contrast, in the Hellenized provinces from the time of Augustus, the living emperor could be referred in Greek *theos,* a god. From its beginning, the emphasis of the imperial cult in the East was heavily oriented toward the current, living ruler, with little regard for the official lists of *divi* issued by the Senate.

Political Aspects of the Cult. An important aspect of the imperial cult was its political nature. Emperor worship was seen by provincial populations as an opportunity to display their allegiance to the ruler in a formalized civic fashion. Some emperors no doubt encouraged it as a means of symbolically illustrating their power far from the capital, and it seems that institution of the cult at a provincial level was an important step in the development of new provinces, especially in cases in which they had been "wild" at the time of their accession by the empire (Fishwick 1987: 148). Further, the cult provided a system within which local aristocracy could relate to Rome and publicly prove their loyalty as well as achieve recognition and social status through participation in the imperial priesthood. By the third century, Cassius Dio (51.20.7) was able to consider worship of the emperor to be one aspect of religion shared by everyone in the empire. Such a factor could prove a very powerful tool for generating a sense of commonality among the peoples of far-flung territories who observed a wide range of religious practices. Judicial and military oaths were sworn to the *Genius* of the emperor, and in some instances the cult was used as a litmus test to prove the loyalty of Roman subjects or to ascertain whether they were adherents of cults considered inimical to the Roman state. In particular, the requirement that individuals offer prayers to or for the emperor in the presence of a government representative was used to discover or prove the identities of Christians, a process discussed in letters the provincial administrator Pliny the Younger (ca. 61–112) wrote to the emperor Trajan (*Epist*. 10.96), and elsewhere. These political aspects of the cult should not, however, be understood to lessen or negate the religious content of imperial worship.

We are particularly well informed about the political significance of the cult in the Greek East, where it provided a framework for negotiating the relationship between the dominant Hellenized culture – which was organized on a city-based system – and the centralized power of Rome. Leagues of cities called *koina* were a feature of the Hellenistic world, and in the imperial period, many of these leagues were organized around participation in the imperial cult. These *koina* competed among themselves for the honor of hosting imperial cult temples, and the cities that won the honor served as the caretakers or wardens of those temples for the entire *koinon.* From the time of Hadrian (r. 117–38 CE), the term *neokoros* (temple warden) was used as a regular, honorific civic title claimed by those cities that had an imperial temple at which a provincial festival took place (the term appears earlier but its meaning was standardized during Hadrian's reign). To be *neokoros* brought a city great prestige, and the title was vaunted in inscriptions and on coinage, a fact that aids us in assessing the range and location of the cult (see esp. Burrell 2004).

In general, though individual emperors had different preferences and also had to be aware of implications for the specific political climate in which they reigned, the tendency to accept divine honors while living became more common as the imperial period progressed (on the evolution of imperial images as a reflection of this shift, see Pollini 2012). Though always more popular in the eastern provinces, altars and temples were dedicated to the living emperor in the West as well, beginning perhaps with a foundation in honor of Claudius (r. 41–54 CE) (at Camulodunum in Britain) but certainly by the reign of Vespasian (r. 69–79 CE) (at Tarraconensis and (probably) Lusitania in Spain and possibly at Narbo in Gallia Narbonensis). As Beard, North, and Price have shown (Beard et al. 1998), whether a particular area of the empire chose to worship the living emperor or to follow Rome in worshiping only deceased and formally deified rulers had less to do with geographical location than with conceptual closeness to Rome. Thus, for example, cults to the

living emperor were established in the West in Germany among the un-Romanized tribes following their conquest by Rome. In addition, practice was dependent on the status of the worshipers who established a particular cult center, especially in the early years of the empire. Therefore, Roman citizens in areas outside Rome, both in colonies and in the provinces, followed Roman tradition in worshiping the emperor, whereas noncitizen subjects of Rome followed local custom. Thus, the Roman citizens in Ephesus in the Augustan period worshiped at a temple dedicated jointly to Divus Julius (Caesar) and the goddess Roma, while noncitizens were free to pay cult to the living emperor. This distinction between worship by Romans and non-Romans later blurred as citizenship became more common in the provinces.

The standard process of establishment of the cult also differed in the East and the West. In formerly Greek areas, the impetus to establish a cult and an altar or temple was almost always local, with the emperor choosing to accept or reject offers as he deemed appropriate. In the West, though there is some evidence of local initiative in establishing the cult in certain cases (e.g., the temple of Augustus at Tarraco in Spain, granted under Tiberius), Rome was more heavily involved in its development and content and, in some areas, seems even to have imposed the cult.

Imperial Cult, Roman, Fig. 1 The head of a priest of the imperial cult in Ephesus in Asia Minor (first c. CE, now in the Ephesus Archaeological Museum, Selçuk). He wears a crown decorated with busts of the imperial family, a common feature of imperial cult priest regalia that is also known from literary descriptions. The heads of the busts were almost certainly destroyed intentionally, probably by Christians. (Photo © Candace Weddle Livingston)

Rites of the Cult. Imperial worship included features of cult rites generally seen in the Roman system. Temples and altars were consecrated to deified emperors and family members. Eleven of the latter were established in the first half of the first century, but their number then decreased markedly, with only four being established after that point. Priests were appointed, drawn from the elite citizenry of the cities in which the cult was celebrated (Fig. 1). The majority of surviving evidence for the priesthood consists of honorific inscriptions noting that individuals had attained the office and specifying the details of their munificence toward their community in providing sacrifices, feasts, and games in connection with the cult. Otherwise, evidence for the range of priestly functions is limited. Their position was one of political as well as religious prestige, as suggested by their appearance in lists of ambassadorial groups and embassies to the emperor. Priestesses served in the cults of the female members of the imperial family, although in one example from Aphrodisias a woman held the priesthood of the emperors, indicating that the gender division was not strict. The titles of some other imperial cult actors are also known from inscriptions, including in the Greek world the *prothytes*, an official of unknown responsibilities related to sacrifices whose title is found only in the context of this cult. Important civic bodies perhaps (as suggested by their name) associated with the cult were the *Augustales*, often understood by scholars to have been associations of ex-slaves who seem to have held responsibilities toward the deified imperial family that included sponsorship of games, building repair, and erection of statues. Though they were active mainly in the West, fraternities of

Augustales are attested in some Roman colonies in the eastern parts of the empire. Beard, North, and Price have urged caution in defining them as associated specifically or exclusively with the imperial cult and have shown that their membership included freeborn as well as freedmen (Beard et al. 1998: 358).

Imperial cult worship included prayers addressed and hymns sung to the *divi*, often accompanied by a range of traditional sacrifices, including offerings of wine or water, ritual cakes, incense, and live animal victims. Oxen were the normal victims offered to a divinized emperor, cows being appropriate for imperial women. Inscriptional evidence indicates that animal sacrifices took place within the cult on a scale up to and exceeding a *hekatomb*, the Greek word for a sacrifice of approximately 100 bovines, though this must have been an exceptional occurrence. The sacrifices took two forms: offerings made directly to the living emperor (or to him and his predecessors as a group) and offerings made to other gods on behalf of the emperor (*pro salute*) to ensure his health and continued reign. Of particular importance in the latter category were yearly *vota* offerings performed on January 3 in both Rome and the provinces to petition the gods for the well-being of the emperors. Interestingly, surviving literary and epigraphical evidence includes only one instance of sacrifice *to* the emperor being performed by a priest of the imperial cult; all other instances of sacrifices performed by imperial cult priests are noted as being completed on the emperor's behalf. In general, it seems that sacrifices to the emperor were less frequent than those directed to other deities for his benefit.

Celebration of the cult was often carried out in the context of imperial festivals. These events, which were held on a regular schedule and could happen monthly, yearly or, for major festivals, biennially or quadrennially, included games and contests as well as processions, sacrifices, and accompanying feasts that often lasted for several days. In the eastern parts of the empire, almost all gladiatorial competitions and wild animal fights were staged within the context of the imperial cult. Festivals were commonly linked to important days in the life of the honoree including birthdays, ascension days, and occasions of good news communicated from Rome to the cities of the empire (e.g., a military victory or the birth or coming-of-age of an imperial heir). A visit by the emperor to a city also resulted in cult celebration (as did, beginning in the third century, the arrival of his image). In some cases, an imperial visit led to the foundation of a new cult sanctuary or provided an opportunity for the consecration of a previously constructed sanctuary by the emperor for whose cult it was built.

The activities of the imperial cult also included Mysteries, about which we have less information. That they formed a regular part of worship within the cult is evidenced by a surviving cult calendar inscribed on an altar of the imperial choir of Augustus and Roma at Pergamum in Asia Minor, on which the Mysteries appear as one of the four most important annual cult festivals. It is also clear on the evidence of this inscription, which includes some details of expenditures on items for the celebration of the Mysteries, that those rites included small-scale sacrifices of incense and cakes. The specification that lamps be provided for the proceedings suggests that the cult image of the emperor was dramatically revealed from the darkness at some point during the ceremonies, an aspect known from other similar Greco-Roman contexts such as the Eleusinian Mysteries (Friesen 2001: 115). The title *sebastophant* (compare the *hierophant* at Eleusis and in other mystery cults) is known from inscriptions, but his duties are not specified.

Chronological Scope. The imperial cult endured as an important aspect of the Roman religious landscape throughout the imperial period, though it did not remain static. Generally speaking, from the birth of the cult under Augustus, a pattern has been noted: a gradual shift from cults of individual emperors toward generic cults of the collective emperors, with Caracalla (r. 198–217) being the last emperor for whom we know of an individual temple or priesthood. Price (1984a) has convincingly interpreted this gradual development as a strengthening of the institution of the imperial cult rather than as a decline in willingness to deify individual rulers.

The end of the cult is difficult to trace. The political and economic unrest of the third century CE affected not only the construction of new sanctuaries but also the celebration of established festivals, which were expensive to organize. The heavily centralized government instituted at the end of that century by Diocletian (r. 284–305) must also have strongly impacted the practice of the cult, particularly in provinces in which impetus for cult celebrations was primarily driven by local devotion. However, important evidence for the continued relevance of the cult in this period is preserved in the province of Egypt at Luxor (see below). The rise of Constantine (r. 307–337 CE) and the increasing political power of Christianity altered the nature and structure of the cult. Constantine's view of the cult is perhaps illustrated by the fact that he allowed a group of towns in Umbria to build a temple in honor of his family but forbade them to offer sacrifices there. Scholars have noted, however, the continuation of certain aspects of the cult in Byzantine court ceremonial, as well as in royal ceremonies of other monarchies through the medieval period, such as those of the Frankish kings.

Archeological Evidence for the Imperial Cult

Worship of the emperor took a variety of forms in different areas of the empire, and archeological evidence has helped clarify the practice and meanings of the cult within various communities in Roman society. Evidence for the cult is rich and varied but also fragmentary, particularly so for the tumultuous third century. The remains of several cult temples have been identified, especially in the eastern provinces of the empire, as have cult statues of imperial family members; images of temples and statues struck on coins provide further evidence. In addition, thousands of inscriptions related to the cult have been recovered, ranging from records of temple dedications to lists of cult regulations. Most of the latter date to the time of Augustus and his early successors. Although the evidence is inconclusive, it is likely that the cult was eventually present in every province of the empire.

Physical evidence for the cult is richest in Asia Minor (modern Turkey), where the results of survey and excavation carried out since the late nineteenth century have clarified both the broad picture of the spread and penetration of the cult and details of its rites and role in the eastern provinces. Surveys show a very wide diffusion of the cult as measured in epigraphical attestation of temples, altars, and priests. The general pattern of the evidence also strongly suggests that the cult was primarily urban and was practically nonexistent in rural areas. This is probably a by-product of the fact that the cult was largely perpetuated and administered by the elite (though there is ample evidence for the participation of individuals from all levels of society). It also highlights the extent to which the cult was derived from and dependent on Greek culture (which emphasized the importance of the city as an institution), reflected a reciprocal relationship with Rome, and required civic organization to function. All of those elements were absent from the more remote areas of the eastern provinces.

Cult Buildings. Following the precedent set by Augustus's construction of a temple to the deified Julius Caesar after his death, nine temples for deceased emperors (sometimes shared with their deified spouses) were constructed in Rome itself. Of these, the best preserved is the temple of Antoninus Pius (r. 138–61 CE) and his wife Faustina the Elder in the Forum Romanum, which was converted into the church of San Lorenzo in Miranda sometime prior to the eleventh century. Elsewhere in the West, temples and altars dedicated to the emperors were constructed from an early date. The first of these was a large and lavish altar to Rome and Augustus consecrated in either 12 or 10 BCE in Gaul at Lugdunum (modern Lyon); its appearance is known from local coinage and from limited archeological remains, which include columns from a later update of the altar under Hadrian that were reused in the eleventh century as supports for the cupola of the Church of St. Martin in Ainay. The altar is notable not only for its scale and opulence but also because of its role as a potent political symbol: it served as a location for 60 Gallic tribes to pledge their allegiance to Rome on a yearly basis. A similar foundation in the Two Germanies at modern Cologne followed

shortly. The cult is also attested in Spain by the reign of Tiberius (r. 14–37 CE) and in Africa Proconsularis under Vespasian, although the dates for the first appearance of the cult in those provinces are unclear. The discovery at Narbonne in 1888 of a fragmentary bronze tablet bearing regulations pertaining to the provincial imperial cult there under Vespasian, a text now known as the *Lex Narbonensis* (*CIL* 12,6038 = *ILS* 6964), provided some specific details such as the cult's festal calendar. It also confirmed the establishment of a cult that included both the Julio-Claudian rulers and the founder of the new Flavian dynasty.

In Asia Minor, 156 temples and shrines have been identified from extant remains, inscriptions, and numismatic and literary evidence, including 52 major neokorate temples in 35 cities. In general, the construction of temples (referred to as *Kaisareion* or *Sebasteion* in the East) reached an apogee in the first half of the second century, which reflects a general increase in civic construction empire-wide during that period. The number of epigraphically attested temple constructions decreases greatly for the second half of the second century and especially for the unsettled third century (however, because the foundation date of a significant number of temples cannot be determined, scholars should be cautious of drawing broad conclusions from the evidence). The forms of the shrines ranged from simple buildings to grand temples on the model of those of traditional gods. Most held images of the emperor and other members of the imperial family.

In addition to individual imperial cult constructions, cult buildings or sacred areas could be associated with sanctuaries of traditional gods, though the imperial *divi* were usually subordinated in some way to those deities. The deified emperor and his family sometimes shared the space of such temples with their traditional occupants, in which case the *divi* appeared either as statues inside the temple itself or in their own building within the bounds of the temple complex. There is evidence in several cases that traditional temples were altered or received structural additions in order to accommodate imperial areas. In other cases, the emperor was associated with the traditional gods in subtler ways, such as through dedicatory inscriptions mentioning both, or by representation in decoration on the exterior of temple buildings.

A particularly interesting example of the alteration of an existing temple – though of a foreign rather than a Roman god – is found in Egypt, where at the turn of the fourth century, an imperial cult chamber with a fine fresco of the first Tetrarchy was constructed within Luxor Temple. Recent restoration (2005–2008) and archeological analysis are clarifying the process by which the imperial cult was overlaid onto the temple that served as the site of the annual regeneration ceremony of the Egyptian state god Amun-Re, reborn yearly in the person of the pharaoh. The selection of the site clearly invited a comparison between the divine aspects of the pharaoh and those of the Roman heads of state, while simultaneously asserting Roman dominance over Egypt and her traditional gods (see Jones and McFadden 2015).

Epigraphical evidence is key to our knowledge of imperial cult sanctuaries. It is not, however, always possible to confirm the evidence of inscriptions in the archeological record. In some instances, it seems likely that the right to construct a temple was granted to a city or province, as indicated by an inscription, but that changing political winds prevented its construction. We are on firmer ground when considering inscriptions that have a high likelihood of having been dedicated or placed after a temple was completed. For example, bases for statues commissioned to celebrate the dedication of a neokorate temple and inscribed with information about the donors of the statues (often, at least in the Hellenistic East, civic or provincial bodies recognizing the granting of a temple to a neighboring body) have been discovered in several cities in Asia Minor. Unfortunately, in many cases the inscriptions are no longer in situ and therefore cannot indicate the location or secure the identification of the temple.

Numismatic finds are helpful in filling the gaps in our evidence, often indicating which temples were constructed and, in some cases, providing details of their appearance. Again, the evidence is particularly rich in the East. Because the granting of a neokorate temple was a high honor for a city or province, it was common for coinage to be

issued featuring the new title of the city (*neokoros*) and, often, an image of the temple itself. In some cases, however, minting of coins may have preceded the actual construction of a temple by a considerable amount of time, meaning that the appearance of temples depicted on coins may be either standardized or based on other existing temples in the area. As with epigraphical evidence, it also seems to be the case that coins were issued for neokorate temples that were never constructed.

The imperial cult was not confined to the precincts of temples. Often, areas for imperial cult ceremonial were installed in civic structures such as (in the East) council houses. Other sites for imperial cult worship included gymnasia, stadia, theaters, and baths. In the East, some cult-related athletic competitions may have taken place in gymnasia, following the Hellenistic model in which competitions in honor of kings were conducted there. The cult was similarly associated with stadia, which served as sites for athletic and musical competitions and animal fights staged as part of cult festivities. However, it is difficult – in many cases impossible – to separate archeological evidence for imperial cult-related events that occurred in gymnasia and stadia from evidence for activities staged as part of other festivals. Literary evidence for sacrifices to the imperial family in theaters and for the placement of their images there is corroborated by the discovery of imperial statues in a theater on Thera and of a decorative frieze with sacrificial and imperial imagery at Hierapolis in Asia Minor. Porticoes were also sites of significance for the cult; some porticoes were purpose-built for the imperial cult, sometimes adjoining a *Sebasteion*. Although this was most common in the Greek East, it is also seen in Italy and North Africa.

In Asia Minor, there is evidence that some type of imperial cult-related activity was carried out in dedicated areas in bath complexes. Dubbed *kaisersäle* ("imperial halls") by archeologists, these spaces range from small rooms to large, richly decorated halls. Particularly fine examples have been excavated at Ephesus and Sardis (Fig. 2). Their identification as *kaisersäle* has been deduced primarily from the presence of inscriptions referring to the *Sebastoi*, and several have niches that probably held images of the imperial family. At least ten of these rooms have been identified so far, one (at Ephesus) with an intact altar, but none with which a surviving imperial statue can be firmly associated. Their function remains a matter of debate.

Cult Images. Imperial cult images took several forms and were displayed in a variety of ways. Some temples arrayed a range of figures along the walls to which additions could be made as necessary, with the scope of representation in some cases even including members of several dynasties. Other shrines exhibited a limited number of colossal figures. Archeological evidence for cult images includes actual statues and fragments thereof, as well as inscribed bases and numismatic representations.

As in the cults of the traditional gods, images of the emperor and the imperial family served as loci for their veneration. Cult images could portray the emperor in a variety of forms, following the standards of Roman portraiture. The objects of cult could be shown cuirassed, nude, or in civilian clothing (that is, the Roman toga or, more rarely and only in the East, in Greek dress). In some cases, the emperor was depicted with covered head (*capite velato*), offering sacrifice as a priest in his own cult; a few imperial temples in Asia Minor had cult statues of this type. Though it is sculptures that have survived in the archeological record, we know from textual sources that paintings of the imperial family also served as cult images, especially in instances when the imperial image needed to be carried to a location for veneration. Cult images ranged in size from busts to colossal statues measuring 7–8 m in height (Fig. 3). In addition to examples located inside temples, imperial cult images were displayed in public areas and carried in procession on important occasions and during imperial cult festivals.

Key Issues/Current Debates

Much modern scholarship on the imperial cult, especially prior to the last decades of the twentieth century, focused on the question of whether the

Imperial Cult, Roman, Fig. 2 View of the central section of the so-called *kaisersaal* in the baths at Sardis in Asia Minor, with a niche for an imperial statue?. (Photo © Candace Weddle Livingston)

imperial cult should be considered *religio*, and cult actions therefore understood as expressions of authentic religious belief, or whether it was a purely political construct in which ritual actions expressed only fealty. The apparent need to understand the two as mutually exclusive arises from Christianizing notions of religious faith as something separate from earthly concerns and, especially, from political thought. An important by-product of this earlier scholarship was the erroneous notion that the imperial cult, with its apparently "faithless" political nature, was a symptom of the decline of classical Greco-Roman religion leading to the eventual "triumph" of Christianity (see esp. *contra* Price 1984a). More recently, scholars have preferred to view the development of the cult as one element of a general restructuring of the Roman religious system at the time of the early principate (Beard et al. 1998).

Another debate involves the nature of the Roman emperor's divinity: was he considered a

Imperial Cult, Roman, Fig. 3 Head and arm of a colossal imperial cult statue of Domitian or Titus, from the Flavian temple at Ephesus (first CE, now in the Ephesus Archaeological Museum, Selçuk). (Photo © Candace Weddle Livingston)

god while living or only after his death? Questions of individual belief are notoriously tricky and ultimately unresolvable, but it is possible to interrogate to some degree the concept of the deification of the emperor as expressed in official language (see esp. Price 1984b) and illustrated in details of cult ceremonial. In brief, the dual nature of the types of sacrificial rites practiced in the cult (that is, the fact that they were offered both directly *to* and *on behalf of* the emperor) suggests that the living emperor occupied a role between that of men and that of the gods. Recent studies of the development of imperial images within the context of the cult, beginning with Divus Julius, have helped illuminate the process by which the Romans came to terms with this new concept of the role of the emperor and developed a standard visual vocabulary for his portrayal in public and private art (Pollini 2012; Koortbojian 2013).

A final pressing issue related to the archeological evidence for the imperial cult is the fact that many of the immovable surviving remains of imperial cult structures are located in the eastern provinces of the empire, including the former province of Syria (on which, see esp. Segal 2013), where archeological sites and cultural heritage are under imminent threat at the hands of the Islamic State (Daesh or ISIS) and other militant groups, raising preservation issues of grave concern for the international community.

Future Directions

Although many details of the imperial cult remain unclear, archeological and literary evidence indicate that it was an important part of the fabric of political and social life in the imperial period. Excavation and publication of numerous related sites throughout the empire continue, as does new study of literary and epigraphical evidence for the cult. In addition to shedding light on ritual practice and its relationship to imperial power, future study of the cult may help clarify aspects of the process of power negotiations between Rome and her provinces.

Imperial Iconography of Byzantium

Antonio Pio Di Cosmo
Universidad de Córdoba, Córdoba, Spain

Introduction

The iconography of the *basileus* enumerates the formal solutions used to describe the portraits of Eastern Roman emperors; the phenomenon is present during the entire "Byzantine Millennium" (Beck 1981). However, the title "*basileus*" can be used just after Heraclius's kingdom (610–641) when it replaces the title of *Augustus*; until that date the definition "imperial iconography" is in use.

Definition

In the Late Antiquity, the image of the emperor and its criteria of representation were revised. The

change took place at a time of transition when the Roman monarchy used pagan motifs, which assumed various and unpredicted meanings, together with Christian motifs. In this way the official *bildprogramm* that introduces formal traditions of the "plebeian language" into the imperial art is redefined (Bianchi Bandinelli 1967, 7–19). These images represent the result of the search for a formal legitimization of the absolute power of the emperors and they are produced to gain public consent: they are elaborated to transmit specific feelings and to strengthen a sense of safety in the community at a time of general instability. In the Late Antiquity, the imperial iconography affects the emotional side of the public and addresses the change of power's perception in the collective subconscious.

Power is represented as a supernatural concession and the person who detains it has to be consequently represented as a supernatural being; this is how the figure of the divine monarch emerges. The imperial iconography has the responsibility to manage this sacred trait and the irrational feelings brought by the mystery of royalty. Under the influence of Neoplatonic criteria, the numeric criteria of proportions are not enough anymore in order to describe the ideal of beauty nor to regulate appearance, shape and balance of the human body (Plotinus, *Enneadi* 1. 6. 8–9). Art has to tackle root causes and erase any carnal element. Iconography overcomes the classical point of view, despite being in continuity with the tradition, through a set of descriptive formulas and rules able to interpret the formal legacy of the classic period. In order to do so, the iconography reinvents the imperial *silhouette* and reinterprets the classical prototypes into drawings not respecting their original proportions. For example, as a result of the transcendent conception of power, the figure of the sovereign is depicted larger than the others. Dimensional gigantism is combined with the alteration of proportions and the anatomical simplification in which the head is usually emphasized. The frontal prospective refers to a symbolic language to communicate the superior *status* of the person represented. The most common form of representation presents a face characterized by very big eyes and a hieratic expression, an elaborated hairstyle and a peaceful attitude, which the body presents the *imperialia insignia*. Through iconography the sovereign and his people visually meet each other, the cult of imperial images and especially of the sovereign's portraits expresses how meaningfully the remoteness of the emperor was perceived.

At some point the imperial iconography creates an image that is compatible with the Christian theory by using the format of the Late Antiquity. Starting from the early Byzantium, the proportion of the articulations is revised by making them longer and that's how the figure of the Adamic man emerges: his face is a long oval and his very small ears want to give the idea of a sovereign whose attention is totally focused on the inner world. Almost represented as a saint, despite wearing a beard, he looks "androgynous" and "ephebic" (Zibawi 1993, 65); the iconography shows that the emperor is the first to be subjected to God's salvation. The person is depicted as a highly spiritual being by representing the *vir spiritualis*. The iconography provides a formal representation of the Christian vision of a transcendent sovereign. As summarized by the deacon Agapitus (*Expositio capitum admonitoriorum*, PG 86 1. 21. c. 1172), "concerning the physical body the emperor looks as any other man, in terms of power of dignity he is the closest to God." The official images have the goal to extend the "mystic materialism" to the art (Gass 1849, 49).

The representation interprets the features of the person portrayed, but it also keeps a relation of similarity so that it's possible to recognize the subject. The connection with the prototype opens the doors to "dissimilar similarities" that place the representation into a surreal dimension (Michelis 1955, 73). Resemblance and the relation of the representation with the person portrayed explain why people would 'fight' against these works of art as if they were human. People would in fact destroy or celebrate imperial portraits. The damnation prescribes the elimination of all images and name of the sovereign from public monuments but not from coins. We can then understand why Andronicus I, in order to gain the favor of the public, asked to be represented as a farmer with a sickle in his hands

and, for the same reason, had the Empress Xenia not depicted in all her beauty.

The application of codified rules to the imperial representation leads to a *ius immaginum*. For instance, the effigy displayed in a forum or other suitable place had not to be close to inappropriate images such as those of actors or dancers (*C. J.*, 1. 29. 5). Effigies could also benefit of the right of asylum gained *per amplexum*, for a good cause (*C. J.*, 1. 24. 1–4; 1. 25. 1a, 386).

The Historical Background

The systematic study of the iconography of *basileus* started in the first half of the twentieth century when Grabar edited a volume that summarized the topic and adapted the so-called "imperial mysticism" to the Eastern Roman Empire'art (Grabar 1936). This area of study established itself through Byzantine studies and it continued with Gerke, L'Orange, Dvornik, and Underwood. Those researchers organized an important convention on the topic at the Dumbarton Oaks in the 1950s.

The iconography of *basileus* expresses by images the thoughts of political scientists on the "sacred" royalty; Carile wrote about a *basileus* initiated to the "mystery of royalty" in 2002 (Carile 2002, 53–95). The topic was then summarized in 2007 by Winter with the expression "touched by God" (Winter 2007).

The iconography of *basileus* outlines a path that necessarily goes through the *habitus* and the *Herrschaftssymbolik* (signs of power). Those elements have been first recorded by Galavaris in 1958 (Galavaris 1958, 99–117) and Pertusi in 1976 (Pertusi 1976, 481–568). Regarding the *Herrschaftssymbolik* of the Late Antiquity, we can point out the recent book conceived and developed by Panella; this publication includes a contribution by Ricci dedicated to the scepter (Ricci 2011, 191–198). In an essay of 2003, Parani has philologically reconstructed the form of insignias (Parani 2003); we can also find essays that analyze specific insignias. In 1935–1936, Condurachi has studied the meaning of *loros* (Condurachi 1935–1936, 35–37). The *orbs* have been the object of Schramm's studies in 1958 (Schramm 1958, 135–156). Crowns have also fascinated many researchers; there was an exhibition dedicated to them and a publication with the minutes of a convention on the topic with contributions by Carile, Piras, Gariboldi and Ghini (AA VV. 2000). Its updated version, the *Kamelaukion*, has attracted the interest of Piltz in 1977 (Piltz 1977). Dagron reconstructs the development of the map in the *akakia* in 2007 (Dagron 2007, 203–220).

The Key Issues/Current Dabates

The doctrinal debate focuses on the interpretation of the imperial figure and on the analysis of the *silhouette* as an ensemble of patterns that are mechanically repeated by setting up, almost unconsciously, a set of rules. This allows us to detect the frequency in the use of certain models as a result of the negotiation between the "producers" and the public as a "consumer." The repetition of the same patterns seems to validate the stereotype of a static Byzantine art, as static as the eastern Roman society pretends to be. In fact the immobility of the Byzantine society is just a myth as proven by an analysis of the outfit of the subjects represented. Clothes follow the fashion of the time and allow us to determine a quite precise chronology of the documents.

The International Prospectives

The iconographic production provides us with a large amount of data; by looking at those data, we can come to the conclusion that when it comes to official images, the iconographic representation usually depicts just one or two essential characters isolated from the overall context; solutions that show the expression of power through *locus* of *majestas* is also preferred. The enthronization of the sovereign is a 'classic' image where the main character is located at the center of the world

(De Champeaux 1981, 394). According to the modality of representation, we can find more emperors sitting side by side to symbolize cooptation or succession.

The iconography produced by the Tetrarchy is centered around the two *Augusti* and the double throne that modifies the function of the consular formula, while the *Dominato* develops the *locus* of the enthronization from the representation of the magistrate that presides the urban games over the *sella curulis*. On the "a gold," coin issued by the Constantinople Mint, a hieratic Constantine the Great is depicted seated on a throne between his sons as *majestas domini*. It is a frontal portrait of the emperor; he holds the scepter with the right arm as a reference to *Jupiter Conservator*. Constantine is not depicted as a naked god, but he wears the civil *habitus* of emperor. The imperial holiness is expressed by the light that surrounds the figure of the emperor. A modality that indicates the divine *sother* and that we can also find in Giovianus iconography.

The *locus* of the enthronization loses its strength and it is not frequently used in Byzantium in the fifth to sixth century. Despite that we can mention the gold coin of Valentinian I and Valens of the Mint of Constantinople at Dumbarton Oaks, both depicted on the double throne wearing consular clothes, we can also admire the representations of Theodosius and Valentinian II of the Mint of Milan seated on a double throne wearing chlamys.

During the Early Byzantium, the proxemics of the enthronization as seen in the *Jovius type* is also used with Justinian I in a *follis* of the Mint of Antiochia: it is a solemn and frontal perspective; the emperor wears *vestis civilis* and holds the orb and the long scepter.

He is also represented in another coin issued by the Mint of Constantinople with Justin I; they both sit in *majestas* on a double throne with the orb.

Justin II is depicted in follies with his wife Sophia since they didn't have any heir. Maurice is also represented with his wife Constantina.

At a certain point, the secular image of the *majestas* on the throne is transferred to the Christian imaginary, since then the *basileus* is always represented standing.

During the Middle Byzantium, the Macedonian dynasty restores the previous model. Basil I gains the throne after the killing of the predecessor Michael III and he chooses to be represented on the throne. His son, Leo VI, will also decide to be represented on a double throne with his heir.

The *topos* of the enthronization survives in the miniaturistic style of the Middle and Late Byzantium. At the end of the Middle Byzantium, Nikephoros Botaneiates asked to be represented in the miniature at the f. 79 of the Code Coislin seated on a throne with the shape of a lyre among eunuch and bearded dignitaries (Fig. 1).

During the Late Byzantium the visual document at the f. 5 of the Ms. Gr. 1242 represents the co-emperor John VI Kantakouzenos presiding a council among bishops and other dignitaries. In these cases, the iconographic choice shows the versatility of the initial *locus* and the possibility to add ancillary elements (Fig. 2).

The iconography of the Byzantine *majestas* also includes the half body representation of the emperor full face. He is depicted standing tall; his figure is still. This *locus* becomes a classic with the only variants of a slight tree quarter, which we can find on seals of Palaiologos' era at the Vatican and a full three quarter in the *Deesis*'s scenes.

The standing figure of the emperor was already present among the sculptures of the Late Antiquity and it can include the garment of *paliatus* as in the statue of the Emperor Julian at the Louvre or as in the Valentinian II of Aphrodisia in *vestis triumphalis*.

The Diptych of Anicius Petronius Probus dated 406 AD instead shows us the image of the Emperor Honorius wearing military clothes.

The image of the standing emperor establish itself as an autonomous pattern just in the Middle Byzantium and the visual documents, especially in numismatic, show two main descriptive typologies: the monarch wearing a chlamys or a *loros*.

The iconography cannot be diminished as motionless and homogenous since the tradition of the representation of the *basileus* is not homogenous. The iconography of Late Antiquity taps

Imperial Iconography of Byzantium,
Fig. 1 Nikephoros Botaneiates enthroned, miniature of the Code of Homilies of John Chrysostom, Manuscript Coislin, f. 79, *Bibliothèque nationale de France*, Paris, (https://it.wikipedia.org/wiki/Niceforo_III_Botaniate#/media/File:Jean_Chrysostome_Hom%C3%A9lies_btv1b8470047d.jpg)

into the Hellenistic shapes and in the so-called sub-ancient, present in provincial styles, which adds a popular expressivity at the expense of naturalism. Motifs such as large eyes in ecstasy, volitive expressions of the face and eloquent gestures all depicted with vibrant colors. The formal modules are blended with the elegance so appreciated by the refined court; the latter was very useful to optimize the esthetic result of the imperial figure.

These motifs became a cachet of the iconographic repertoire and were passed to the Early Byzantium, when they had been renewed by the repetition of a series of stylistic features that suggest an "eternal Hellenism" (Kitzinger 1967, 357–388): a Hellenism that leads to a series of so-called renascences.

From the end of the Early Byzantium until the "renascence" of the Palaiologos, the iconography of the *basileus* employs stylistic features that recall a medieval Hellenism reduced to part of the body engaged in movements that often appear mechanical. Standardized poses are chosen for artistic reasons and make the narrative of the representation more powerful.

In order to give a more accurate timeframe to these representations, it is necessary to analyze the evolution of all the things worn by the *basileus* and his insignias.

The iconography of the Early Byzantium doesn't follow the classical ideas of simplicity when it comes to clothes; in fact, it favors complexity and ostentation. So we can find three types of garments: military uniform, triumphal outfit and civil costume.

Military uniforms are an essential part of the representation of a monarch that faces the army, as recalls Theophylact of Ohrid (*Opera*, vv 21–23; Gautier 1980). Looking at his image, it can be noted how his military costume looks more like a parade costume, not very functional for a battle; nevertheless by wearing it, the emperor can be easily identified as victorious while leading his army.

Imperial Iconography of Byzantium, Fig. 2 John VI Kantakouzenos presides over a council of bishops and other dignitaries, miniature, Ms. Gr. 1242, f. 5, *Bibliothèque nationale de France*, Paris, (https://upload.wikimedia.org/wikipedia/commons/2/22/John_VI_Kantakouzenos.jpg)

The military garments of the Late Antiquity include an armor, a *paludamentum*, a not very long purple cape and shoes, such as *coturni* decorated with lion cubs' skin. The effigies also include a diadem called *toupha* or *pilleus pannonicus* (cylindrical headpiece) as in the Tetrarchs' representation of Venice. The helm appears in the Constantinian numismatic. Under the influence of Ambrose (*De obitu Theodosii*, 40–48), the helm is often used by Justinian and Maurice.

The Barberini ivory can be considered a paradigmatic representation of the military clothing in the Late Antiquity and Early Byzantium. It represents the Emperor Anastasius holding a diadem; he wears a tunic under his armor and a cape (*paludamentum*) fastened on one shoulder; the tight armor has thin *segmenta* (strips of leather) and shows the shape of the muscles beneath it; and his boots are decorated with ornamental lion's heads (Fig. 3).

Military clothing changes in the Middle Byzantium. The new style can be seen in a miniature of the *menologium* of Basil II, BNM, Ms. Gr. 17 at f. 3r (Fig. 4). The tunic is dark purple, it has long sleeves down to the knees and it is decorated by *armillae* and a golden *lacinia*. The armor is made of golden scales and covers half of the quadriceps; the parade shafts are embellished with pearls. The large purple cape is tight on the chest. The miniature of the *Skylitzes Matritensis* that depicts Theophil presents a similar armor, so we can deduce that military clothing didn't change much until the beginning of the Last Byzantium.

The imperial outfit of Late Antiquity includes the use of a triumphal robe that follow the *formula consulatus*, which is decorated with precious details such as pearls and jewels on the *trabea* and purple sandals, while the ordinary consul wears white leather *calcei*. Synesius said that the sovereign wears a triumphal outfit (*De regno*

Imperial Iconography of Byzantium,
Fig. 3 Barberini ivory, anonym emperor often identified with Anastasius (https://it.wikipedia.org/wiki/Avorio_Barberini#/media/File:Diptych_Barberini_Louvre_OA9063_whole.jpg)

c. 16) every time he goes to the senate and his clothing is so distinctive that becomes *locus*. According to Dionysius of Halicarnassus (*Antiquitates romanae* 3. c. 61. 1), the toga decorated with palm trees (*vestis palmate*) is similar to the "χιτώνα τε πορφυρούν χρυσόσημον" of the early Roman kings; this robe is called *toga picta* by Ausonius (*Liber proptrepticus ad nepotem* 13. 90) because of its purple color.

The *trabea* of Late Antiquity is a circular cloth that it is wrapped around the body several times to reshape the shoulders and its components are the *balteus*, the *remeatio* (at the back) and the *tabula* (from the shoulder to the chest); there is also a train that goes on the arm: the *falda*. The material is usually embellished by a motif of small roses in geometrical shapes; this motif is called *segmenta*. The ornaments can also present anthropomorphic and aniconic motifs as the busts inscribed on the *trabea* of the emperor-consul Constantius II, which appears at the f. 20 in the calendar of Philocalus.

A purple surcoat is added to the ensemble of the Late Antiquity: the *colubium*, this garment is enriched by gold braids around the neck and along the bottom edge together with rich trimmings. Surcoats don't have sleeves in Eastern countries, while they have very short sleeves in Rome. According to Lydus (*De Magistratibus* 2. c. 2), a triumphant Justinian wears a purple tunic, a gold woven *colubium* and a *loros*. The choice of a different name for piece of clothing such as the *trabea* is an evidence of the intention to create the *loros* costume as a distinct outfit, which matures in Early Byzantium. When the consular office was suspended by Justinian, the *vestis triumphalis* didn't disappear but gradually was not part anymore of the triumphal rite. Those garments found a new context and meaning in the Christian environment and became the Eastern *habitus* of *basileus*.

During the Late Antiquity, the emperor also wears "civil clothes" when representing the maximum authority in the administration of the state.

Imperial Iconography of Byzantium, Fig. 4 Triumphant Basil II, Psalter of Basil II, BNM, Ms. Gr. 17, f. 3r (https://commons.wikimedia.org/wiki/File:BasilII.jpg)

As a public official, he wears a short white tunic made of silk decorated by gold *segmenta* (*clavi*). Lydus (*De magistratibus* 1. c. 17) provides us with a detailed description of the outfit: a purple chlamys embellished by a *segmentum* or *tablion* (*De magistratibus* 2. c. 13), a fibula (mentioned by John Chrysostom in *epistula II ad Thessalonicensis* c. 2), among other *imperialia insignia* and the sovereign holds the chlamys on the right shoulder. This garment is a *status symbol* of Early Byzantium too, with its purple *campagi* adorned with precious stones and the *stemma* (a crown). The red leather belt, called *cingulus* or ζώυη, together with the golden brooch, is also a symbol of the status of *illustres*. This outfit is known as chlamys costume.

The *basileus*' iconography of the Middle Byzantine period shows a very large imperial wardrobe (Constantinus Porphyrogenitus, *Liber de caerimoniis* 1. 46. 37). Among those garments, there is the *skaramagion*, a long and tight tunic with a narrow waistline. This tunic in purple and the *loros* are usually worn at Easter; it is a classic *locus* to see them worn by the *basileus* when he indicates the *Typus Christi*.

By looking at the *Constitutum Constantini* and considering the wrong reference to the *frigium*, we can deduce that the *loros* represents the funeral bandages illuminated by the light of the Risen Christ and Sun of Justice (*Constitutum Constantini* 257). The *loros* also assumes a "Y" shape and from being a large circular cloth, it is turned into a scarf worn around the body. The folds crossing the chest remind of the *remeatio* and the *balteus* of the *trabea* and the drap on the left arm looks like a *falda*.

Toward the end of the Middle Byzantine period, the *loros* is transformed into a long

scapular and it is combined with a *maniakis* (collar). The edge of the back side of the scapular is worn around the waist and on the left forearm; it replaces the *falda*. We can admire this style in the representation of John II Komnenos in the mosaics of S. Sophia's gallery (Fig. 5) and in a miniature at the f. 2 of the Cod. Vat. Gr 1176.

The iconography of the *basileus* also presents the *divitision* over the *skaramagion*; this robe recalls the Western Dalmatian garments. This combination together with the chlamys are the outfit worn at the most important parties and it is called the chlamys costume.

A rare element in the wardrobe of the *basileus* is the *thôrakion*, a sort of armor that in the tenth century was basically a corselet made of material cut in an oval shape and decorated with a golden thread, more common among the *basilissa* rather than among *basileus*. Another garment that seldom makes its appearance is the *kolobion*; in fact, the only thing that differentiates it from the *skaramagion* is the *clavi* at shoulder height. This element is present until the last period of the Byzantine Empire and it is somehow similar to the monastic *habitus*, the dark *sakkos* (ῥῦοχον κόκκινον) that we can find in the *basileus*' iconography of the same period.

Imperial Iconography of Byzantium, Fig. 5 John II Komnenos, mosaic, Gallery of Santa Sophia, Istanbul, (https://it.wikipedia.org/wiki/Giovanni_II_Comneno#/media/File:Jean_II_Comnene.jpg)

The chlamys costume goes out of fashion under Manuel I Komnenos and it is replaced by the *loros* costume. The last iconographic representation of the chlamys is in a manuscript of the Vatican (Gr 6c6 at f 2r of the 1109–1111), where Alexander I Komnenos is still wearing it. Iconographic documents with chlamys costume produced after this date replicate a model that is out of fashion, but they mirror what is still a common social expectation. Several visual documents attest the interchangeable use of *loros* costume and chlamys costume, despite the strict rules of the protocol. The combination of the two in the iconography is probably due to an iconographical license due to the transitional period. We find examples of this transition in numismatic representations and in the tonds at the Dumbaton Oaks and Calle Angaran in Venice.

According to Parani the recapitulation of Constantinople in 1204 leads to the decline of the chlamys costume since it represents an emperor administrating a system that is collapsing.

The *basileus*' iconography switches to a more efficient formula by depicting a victorious emperor, protector of its people and peacemaker, a *Typus Chisti* explained by the *loros* costume (Parani 2003, 15–16).

In the last period of the Byzantine Empire, the *loros* evolves and it is called *diadema*. The new version is a belt with a wide drapery that is worn on the left forearm as a reminder of the *falda.*

The chlamys is now a piece of garment used by members of the court who have lower positions, *despotes* and *sebastokrator*, as attested in the miniature at the f. 2 of the Code Ivories a53 (Fig. 6). The chlamys was also called *porphyras* during Palaiologos' time.

With the redefinition of the insignias of power between the Medium Byzantine period and the beginning of the Last Byzantine period, the name purple *pedilia* is changed into *tzangia*. The iconographic documents of Palaiologos' time show shoes embellished with pearls and cross-shaped jewels; from literary sources, we also came to know of golden embroidered eagles and pearls even on socks.

Imperial Iconography of Byzantium,
Fig. 6 Manuel II Palaiologos and his family, 15th sec., miniature of the Code Ivoires a 53, (o 100) f. 2, Louvre, Paris (https://it.wikipedia.org/wiki/Manuele_II_Paleologo#/media/File:Manuel_IIHelena_sons.JPG)

The most important element in the representations is the crown. Constantine, as *ierofantes*, introduces the *teniè*-diadem, a sign of sacrality similar to the sacerdotal *infula*. The corona triumphalis is so replaced as a symbol of the *status* of "universal bishop" (Eusebius Caesariensis, *Vita Constantini* 4. 24). In the Late Antiquity, there are two variations of this kind of *insignia*: one with a hinge closure worn on the head by Magnentius in the Vienne lapidary and by the sculpture of Valentinian II of Budapest. The other one has a seam at the back of the head and is embellished with pendants that rarely appear on sculptures.

During Early Byzantium with Justinian I and probably even with Anastasius I, we have a crown in the shape of a rigid ring decorated with jewels, *prependulia* (short pearl pendants on the sides) differentiate it from the Greek *stephanos*.

A variation of the *insignia* presents peacock's feathers; this ornament is called *toupha* and is worn by triumphant emperors. Procopius of Caesarea (*De aedificiis* 1. 2. 10–12) described this as a detail of the statue of Justinian I at the *Augusteon* and it is also present in a drawing at the f. 144v of the Cod. Ital. III of Budapest dated 1340.

Starting from Heraclius, the crown is made of several plates hold together by seams; the model is probably inspired by the *insignia* of the Sasanid and Kushan kings.

During the Middle Byzantium, the *insignia*, worn by Constantine IX in the mosaic of S. Sophia's gallery, reminds the crosses that decorate the crowns of the *pentapirgion*; it presents a golden ring embellished with pearls and jewels. In the

middle of which stands a larger gem encircled by pearls and surmounted by a cross, *prependulia* (called *ormathoi* at that time) decorate the sides (Fig. 7).

At the end of Middle Byzantium, under Alexius Komnenos the crown is called *kamelaukion* and assumes a spherical shape. Such a change took time to become popular and in the iconography of the *basileus* intended for a wide circulation, appears only on the Palaiologos' numismatics.

The iconography of the *basileus* includes the use of the orb as a symbol of sovereignty over all things and distinctiveness of the "human kingdom." This *insignia* has not been recorded by John Crysostom (*De Perfecta Charitate* 6 PG 56. 287 a) among the insignias of power of Late Antiquity, and this leads to question its use. On the other hand, this symbol is valued in numismatic. The cross on the orb becomes a sign of power that gives strength. The word "PAX" is written on a coin of Justinian II and reminds to a *pacificator orbis* emperor.

Imperial Iconography of Byzantium, Fig. 7 Constantine IX Monomachos, mosaic, Gallery of Santa Sophia, Istanbul, (https://it.wikipedia.org/wiki/Costantino_IX_Monomaco#/media/File:Emperor_Constantine_IX.jpg)

During Middle Byzantium a mosaic in S. Sofia depicts Alexander, the son of Basil I, wearing his Easter clothes and showing the orb and the *akakia* as an alternative to the scepter with the cross (Fig. 8).

Akakia (guilelessness) and *anexikakia* (forbearance) (Philoteus, *Kletorologion* 8–9) are an *insignia* that symbolizes the limits of the powers of the sovereign. The *akakia* is represented as a purple cylinder, referred to as a map by the scientific literature; it is hold by the "man of power." In the diptychs it is described as accurately folded. It is possible to see it on the consular ivories at the right side of the magistrate that organizes the games. The *album pannulum* also becomes purple when it is hold by the emperor. There is a clear distinction between the *akakia*, which is a sign of instability of power that is transmitted from one person to the other and the handkerchief. During

Imperial Iconography of Byzantium, Fig. 8 Alexander, mosaic, tenth century, Santa Sophia, Istanbul (https://it.wikipedia.org/wiki/Alessandro_(imperatore)#/media/File:Alexandros_mosaic_Hagia_Sophia_edit.jpg)

the Middle Byzantium, the *akakia* is also described as a golden box that contains soil. We also know of an *insignia* called μαξιλάρια, a pillow filled up with sand or soil. The *akakia* can also be represented as the roll of the law of salvation, law enforced by the Christian emperor: an *insignia* that reinforces the Easter *Christomimesis* (Dagron 2007, 218).

The symbol of the cross as a trophy highlights the religious pietas of the *basileus* in his official image as an "orthodox" sovereign; the cross represents his faith in Christ. The processional cross was introduced by Theodosius II, while Leo I used a golden *stauròs* (cross) at imperial processions. In a solidus (gold coin) issued by the Mint of Constantinople Irene holds a simple cross compared to the one of Justinian II, which holds the Calvary in his hand. Theophil introduces a cross characterized by the so-called "patriarchal" shape; this cross is made of a double crosspiece.

With Constantine IX the cross-shaped *Cymatium* of the scepter is decorated too by a motif that reminds to the cross anchor as attested by a *Histamenon Nomisma* (gold coin of the IX century) issued by the Mint of Constantinople.

A long two spheres scepter is a symbol of the dead sovereigns in the roman imperial iconography; it represents their divine nature. This *insignia* is not reserved to the sacred imaginary. Trajan wanted to be depicted on a coin with the two spheres scepter seated on the *sella curulis*. The *insignia* appears during Late Antiquity on the gold coins of Constantine the Great and on those of his children Constantius II and Constans. The scepter also appears in the Rothschild cameo of the 398 AD and Honorius holds it in the diptych of Probus dated 406 AD.

A modified version of the two spheres scepter is hold by the emperor when wearing military clothes; this is also the characteristic of the *Prince Juventutis* since Domitian.

During the Early Byzantium, this specific scepter is attested in the consular diptych in Museum of Bargello dated 500 AD; in this representation an empress holds it with her left hand; it will later appear in the coins of Justin II and Constantine IV.

Despite the pagan origin, this *insignia* is perceived as Christian; it is in fact often mistaken with Moses' rod. It is considered a religious symbol carried by the emperor in order to represent his function as spiritual guide with *in sacris* powers. It doesn't have to be confused with the *narthex* given to *deputatos* at the end of the Middle Byzantium. Moses' rod is on the other hand symbolized by a stick with plume or tipped with a flower as those represented in the coins of Constantine VII and Constantine IX. Under the rule of the Komnenos, a new variation of the scepter with three globes placed one on top of the other also appears on the coins.

It is also worth mentioning the *labarum*, an *insignia* that according to Eusebius' contested statement was ordered to be made by Christ (*Vita Constantini* 1. 29. 60). In the *labarum*, a long *stulis* (spear) is crossed by a transverse bar; at the top of this bar, there is the *supparum*, a purple veil. The *insignia* that accompanied Constantine after his success in the Late Antiquity disappears and it is then introduced again under the rule of Theophil. This revival under the Macedonian dynasty has been defined as "nostalgia of the symbols of Constantine" (Galavaris 1958, 108).

The Future Developments

The future research will look at the connections between the iconography of the *basileus* and local monarchs of the Byzantine *koiné* area. The latter are in fact inspired and shaped by the criteria of representation of the *basileus*, as a consequence the *silhouette* of the local royalty and its insignias are directly dependent on it.

In Situ Preservation of Shipwreck Artifacts

Ian D. MacLeod
Western Australian Maritime Museum, Fremantle, WA, Australia

State of Knowledge and Current Debates

Introduction

One of the consequences of adoption of the 2001 UNESCO Convention on the Protection of Underwater Cultural Heritage is that the convention's strong emphasis on nonintervention on the site of an historic shipwreck can at times lead practitioners and heritage managers down to a very narrow management path (UNESCO 2001). The argument that there is a sufficient body of knowledge on naval architecture as to render detailed site recording obsolete misses the point of maritime archaeology as a discipline. If work on in situ corrosion surveys of shipwreck sites is precluded on the basis that even this form of minimalist intervention is not essential, the loss of data about the present and long-term corrosion of metals on a shipwreck site will condemn management into making misinformed judgements. The arguments put forward in the body of this chapter make a compelling argument as to why the corrosion and concretion matrices on artifacts present a highly valuable data set of unique cultural insight into the fabrication, use, and decay of the variety of elements that make up a shipwreck. Judgements made without full evidence of site formation and disintegration processes are prone to systematic errors which will ultimately hasten the demise of the wreck site and with it much of the loss of cultural information. To disregard this record of deterioration is akin to cultural vandalism.

Analysis of Corrosion Profiles to Provide Site History

All metals used in the construction of ships and their fittings were commonly mined as oxides,

sulfides, chlorides, and carbonates. Metals are formed when chemical reducing agents, such as charcoal or coke, react at high temperatures and transfer electrons into the minerals and so create the parent metals. The inherent reactivity of elements is modified by alloying them with other metals, in the case of formation of bronzes from copper and tin making objects more able to be cast or fashioned into functional objects (Tylecote 1977). Addition of unreactive carbon to iron results in a vast array of functional alloys ranging from wrought iron, cast irons, to structural steels. A variety of heat treatments can alter the microstructure of the iron-carbon alloys which in turn affects not only their hardness and ductility but also the rate at which phases with dissimilar composition corrode. Preferential corrosion reactions are most commonly manifested in the form of graphitization of cast iron, where the outermost parts of the surface have lost all or most of their iron content. It is the preservation of this layer that is vital for conservation of cast iron artifacts since all foundry marks are retained in the degraded matrix. These layers also provide an accumulation index of the corrosive forces on the wreck site (MacLeod 2006).

When metals are fabricated through hammering, drawing, and rolling, the underlying microstructure changes, and if the imparted stresses are not relieved by heat treatment after fabrication, stress corrosion will manifest itself as a series of finely etched lines on copper fastening bolts or as cracks around the heads of drifts and clinch rings. Corroded silver coins can show up corrosion stress patterns imparted by defects in the rolling phases if the coins are circulated in an unannealed state after manufactures (North and MacLeod 1987). However, practitioners have cause to be grateful for the varying degrees of technical skill associated with artifact manufacture since preferential corrosion along stress or compositional gradients produces decay patterns that enable rapid nondestructive analysis of the methods of artifact manufacture. All metals on shipwreck sites have a variety of different phases of varying corrosion resistance which are very sensitive to changes in the amount of water movement across a site which can result in banded layers of corrosion products. The varying depth of archaeological sediment on the wreck of the American China Trader *Rapid* (1811) resulted in preferential corrosion of the copper-rich alpha phase in exposed conditions and corrosion of the ($\alpha + \delta$) eutectoid when the bronzes were corroded in a low-oxygen microenvironment under several centimeters of sediment (Taylor and MacLeod 1985). When metals of significantly dissimilar electrochemical potential (voltage) are contiguous, the more reactive metals, such as iron alloys connected to copper alloys, will be preferentially corroded which often results in the complete mineralization of the iron phases and cathodically protected copper alloys. This form of reaction most commonly occurs with iron clappers in bronze bells and with iron frames connected to bronze rudder fittings in composite shipwrecks – the archaeological advantage of such processes is that the concreted iron fittings can be replicated through creating cast replicas of the interior of the concretion, while the protected components typically need one-tenth the amount of treatment time as identical alloys from other shipwrecks (MacLeod 1987) (Fig. 1).

Proximity corrosion is galvanic coupling through the matrix of artifacts, ballast mounds, and marine concretions found on historic shipwreck sites and on offshore production platforms and can be used to explain apparently anomalous corrosion performance of ordnance (North 1989).

In Situ Preservation of Shipwreck Artifacts, Fig. 1 Bronze dovetail fittings from the wreck of the *Rapid* (1811) showing differences in corrosion mechanism between partially aerobic (*vertical fittings*) and fully aerobic (*horizontal*) burial microenvironments. (Photo: Patrick Baker, Western Australian Museum)

Cannon on the *Rapid* (1811) wreck site at Point Cloates in Western Australia exhibited corrosion rates up to three times higher than that observed on guns in a similar archaeological profile owing to the proximity of thousands of copper nails, drifts, and spikes in the carpenter's store (Carpenter and MacLeod 1993). Galvanic corrosion can be more subtle in its effect for when the relative corrosion rates of the boiler water feeder heater, with its attached copper heating coil, were compared with the engine, which was in a similar burial and current microenvironment, the cast iron water heater was corroding at 0.196 mm. year$-^{1}$ which is double that of the engine whose long-term corrosion rate was 0.094 mm. year$-^{1}$ (MacLeod 1990). Sixteen corrosion layers of the copper (I) sulfide Cu_2S chalcocite found on a brass tallow pot followed the Liesegang pattern of periodic precipitation covering the 112 years of immersion, i.e., an average of a 7-year cycle. The wreck site of the SS *Xantho* (1872) is subject to changes of ±2 m in the sediment depth; thus, the corrosion bands are due to anaerobic corrosion when the engine is periodically buried since the normal cathodic protection provided by the cast iron engine is lost under the impact of the sediment on the Penn horizontal trunk engine (MacLeod et al. 1986) (Fig. 2).

In Situ Corrosion Measurements and Development of Site-Specific Data

In situ corrosion studies provide data to give an insight into the past and present rates of deterioration of the metallic components. Information pertaining to the corrosion potential (E_{corr}), the pH, and the profile thickness of the combined layers of corrosion and concretion (t_{mm}) provide a remarkable insight into the decay processes. Corrosion of metallic artifacts, including whole iron and steel ships, is dominated by the reaction between the underlying metal and the amount of dissolved oxygen that is passing the concreted metal surface. Marine concretions consisting of an admixture of metal corrosion products and the reaction products of these compounds, with the calcareous substrates deposited by encrusting marine organisms, are electrically conducting. This matrix provides a path for electrons to move from the corroding metal to the dissolved oxygen in the immediate vicinity of the artifact. The voltage of the corrosion cell (E_{corr}) depends on the nature of the underlying metallic object and the flux of dissolved oxygen to the concretion interface. In anaerobic environments the corrosion potential still depends on the oxidation of metal and but it is the reduction of water and not that of dissolved oxygen which is the cathodic process. The voltage is normally measured using a platinum electrode and a reference electrode such as silver/silver chloride (Ag/AgCl) which is separately calibrated to correct for sites which have different temperatures and salinity of the seawater. Details of the methodologies involved in drilling through the concretion and corrosion layer have been previously reported (MacLeod 1989, 2006).

Entrained water reacts with metal corrosion products underneath the protective cover of the concretion to produce a series of mixed chloride and hydroxide species and free hydrogen ions. There is a direct relationship between the underlying metal corrosion rate and the pH of the metal interface which is measured directly after the concretion layer has been drilled through (MacLeod 1995, 2006). Different alloys have their own

characteristic pH values so data from different wreck sites need to be grouped according to the same type of basic composition. After decades of immersion, metals can be considered to be corroding at a quasi-equilibrium rate and that the pH relates to the local corrosion cell, whereas the E_{corr} value can be a reflection of a larger area where structural components are electrically connected to each other with sound metal to metal bonds. A corollary of the common nature of the composition of the concretion layer is that thicker total concretion and corrosion thickness or t_{mm} values reflect underlying differences in the local corrosion rate. Data obtained on the wreck of the USS *Arizona* (1941) in Pearl Harbor (Johnson et al. 2006) and from the shallow water wreck of the breastwork Monitor-style warship HMVS *Cerberus* (1926) in Port Phillip Bay (MacLeod and Steyne 2011) has shown that that thicker concretions correlated well with more anodic (more corrosive) values of E_{corr} and with lower pH or more acidic microenvironments due to increased corrosion rates. Thus, protuberances on the sides of iron ships, irregular lumps on cannon, and other artifacts are due to the effects of localized or pitting corrosion of the underlying metal which act as indicators of where not to attach lifting bags during recovery operations.

Effects of Temperature, Salinity, and Stress on Iron Corrosion Rates

Iron shipwrecks provide a wealth of cast iron fittings from which it is possible to obtain a series of corrosion profiles, after removal of the concretion layer and drilling into the graphitized zone of the artifact and the recording of the corresponding pH and E_{corr} data. Linear regression analyses of the data show that the logarithm of the corrosion rate, measured in mm year^{-1} of immersion, is directly proportional to the E_{corr} values in the form of Eq. 1:

$$log\ d_g = a\ \mathrm{E_{corr.}} - b \qquad (1)$$

where d_g is the corrosion rate of the graphitization depth in mm (hence the subscript g) divided by the time lapse between the date of wrecking and the date of recording the data. The value of b depends on the amount of water movement on the wreck site which is also dependent on the water depth and wave action. The constant a is determined by the concentration of dissolved oxygen, which in turn is dependent on both the temperature and the salinity of the water, as reported by MacLeod in 1995. The value of a is given by relationship shown in Eq. 2:

$$\partial\, log\ d_g / \partial \mathrm{E_{corr.}} = 10.33\ log\ [\mathrm{O_2}] - 4.57 \qquad (2)$$

where the concentration of oxygen is recorded in cm^3 dm^{-3}. This equation enables the impact of any seasonal differences in salinity and temperature to be calculated and incorporated into the interpretation of the in situ corrosion data. The shift in the value of E_{corr} needed for a tenfold increase or decrease in corrosion rate is the reciprocal of a, the value of which ranges from 420 mV at 28 °C to 327 mV at 18 °C. Within the accuracy of ±0.002 V for repeated measurements of the same object over several years, a change of only 3 mV equates to 1.6% for the warmer site and 2.1% for the cooler site.

The Japanese iron shipwrecks in Chuuk Lagoon in the Federated States of Micronesia provide a series of corrosion experiments where the impact of the site deposition processes can be assessed through the way in which the corrosion rates vary according to the wreck orientation. Since most of the wrecks were created during "Operation Hailstone" bombing raids in 1944 (Jeffery 2004), there are major parts of the hull plates that are still electrically connected to each other which makes the interpretation of the E_{corr} values difficult. However, this is not the case with the pH values which showed there were linear correlations between the log of the annualized depth of corrosion, d_g, and the pH of the concreted metal. In the case of cast iron fittings on the torpedoed wreck of the *Fujikawa Maru*, the relationship took the form of Eq. 3:

$$^{Fujikawa\ Maru}\log\ d_g = 0.758 - 0.260\ \mathrm{pH} \qquad (3)$$

I

Thus, analysis of the pH values of the corroding hull plates provides heritage managers and archaeologists with an insight into the materials performance and the consistency of the corrosion microenvironment. Similar correlations between the pH and the depths of graphitization have been found for iron cannon from the Cromwellian shipwreck *Swan* (1653), but in this case, the strong currents associated with the ebb tide in the Sound of Mull and the higher concentration of dissolved oxygen in the colder Scottish waters meant that the corrosion rates were much higher than in the sheltered very warm waters of Chuuk Lagoon (MacLeod 1995).

Effect of Water Depth on Corrosion Rate

Although MacLeod had previously developed equations that indicated that the corrosion rate for historic iron shipwrecks in the open ocean fell off as a quadratic function of increased water depth (MacLeod 1998), the elimination of so many of the site variables in the Chuuk shipwrecks enabled a new understanding to be developed. The Japanese shipwrecks sunk in 1944 all followed the same logarithmic relationship between the corrosion rate and the water depth over the first 20 m, as given by Eq. 4:

$$^{\text{Chuuk } 0-20\text{ m}}\log\, d_g = -0.731 - 0.0181\, d \quad (4)$$

with the corrosion rates (mm/year) determined through the extent of graphitization of cast iron elements on the wrecks and d is the depth (meters) at which the depth of graphitization was measured. The R^2 value for this relationship is 0.9849, which is a remarkably good fit given the very different nature of the sites and the errors associated with determining average long-term corrosion rates. The slope of -0.0181 ± 0.0010 for the logarithmic corrosion plot means that the corrosion rate falls by approximately 4.2% per meter. The intercept, i.e., the corrosion rate at the seawater–air interface, had a value of -0.731 ± 0.012, which equates to an annual corrosion rate of 0.186 ± 0.005 mm/year for wrecks laying half in and half out of the water. The logarithmic drop-off in corrosion rate with increasing water depth makes good sense in terms of the rate at which wave action and thus the flux of dissolved oxygen fall off with increasing water depth. When the data from open-ocean shipwrecks was replotted, there was also a linear relationship between the logarithm of the corrosion rate and water depth, given by Eq. 5:

$$^{\text{Open-ocean}}\log\, d_g = -0.630 - 0.0156\, d \quad (5)$$

The corrosion Eqs. 4 and 5 make intuitive sense since the decay mechanism of corrosion is being controlled by the flux of dissolved oxygen which is not unexpected as the basic relationships should be very similar in both these types of environments. With the acquisition of corrosion data from the wrecks of the USS *Monitor* (1862) and the submarine HMAS AE2 (1915), both at a depth of 72 ± 2 m, it was found that Eq. 5 predicted the corrosion rates to within 5% of that which was experimentally measured with ultrasonic metal thickness gauges (MacLeod et al. 2008; MacLeod 2010a). Because the data is empirical, all the natural variations in colonization, water temperature, dissolved oxygen, and water movement have all been integrated into the observed corrosion profiles (Fig. 3).

The differences between the Chuuk slope (Eq. 4) and the open-ocean slope (Eq. 5) are statistically significant which means that the corrosion rate for shipwrecks in Chuuk Lagoon decreases 16% more than for open-ocean wrecks per meter of increased water depth. The lower corrosion rate of the Chuuk sites is due to the more sheltered nature of the lagoon waters which also has a low diurnal tidal range. The differences in the intercept values of the equations equate to Chuuk wrecks having a 21% lower corrosion rate for wrecks in the splash zone. Previously torpedoed and repaired vessels, such as the *Shinkoku Maru* and the *Yubae Maru*, appear to be corroding faster than vessels that had no previous history of physical damage. It is likely that stresses in the steel, from the accumulation of either stress from having been blown up and repaired or the stresses associated with the catastrophic shipwrecking processes, are being reflected in elevated corrosion rates.

In Situ Preservation of Shipwreck Artifacts, Fig. 3 View from interior of bridge on the *Fujikawa Maru* in 2002 during initial corrosion survey. (Photo: Bill Jeffery)

Concretion Microenvironment

After many years of hydrolysis of corrosion products underneath the protective concretion cover, the interstitial solutions become rich in chloride ions and hydrogen ions as the concretion acts like a semipermeable membrane (North 1976). The bore solution from a sealed iron cannon recovered from the turbulent *Zuytdorp* (1712) site had zero dissolved oxygen and a chloride content of 54,593 ppm, which is nearly three times as much chloride as in normal seawater (MacLeod 1996). The concentration of $FeCl_2$ solution was 1.54 M, and the pH of 4.8, due to the hydrolysis of the ferrous chloride primary corrosion products, is consistent with the species distribution reported by Man-Seung (Man-Seung 2004). As the corrosion products diffuse away from the metal surface and approach the cathodic outward surface, the residual oxygen concentration increases to allow the formation of green rust of the general formula $\{Fe^{II}{}_3Fe^{III}(OH)_8\}^+\{Cl.H_2O\}-^1$, but these products exert minimal influence on the corrosion mechanism. Analysis of the pH data from the *City of Launceston* wreck showed that certain parts of the wreck were corroding at a faster rate and that these zones correlated with localized turbulence associated with the currents in and around the high profile of the intact clipper-styled iron steamship. Measurement of residual metal thickness of the hull plates in these zones confirmed that the pH values were indicative of long-term corrosion trends (MacLeod 2002).

Monitoring Changes on Wreck Sites

Through periodic assessments of shipwreck sites, it is possible to determine if there are any changes occurring that are otherwise not readily discerned by a diver swimming across a wreck site. During an 18-year program on the wreck of the *City of Launceston* (1865), the cessation of scallop dredging resulted in a 22% drop in corrosion rate, due to improvements in water clarity which lead to more effective covering by marine growth. Allocation of extra resources to a 2-year program of detailed mapping of the wreck site resulted in an unanticipated increase of 43% in the corrosion rate, slightly exceeding the value when the scallop dredging was active. It was extensive hand clearing of the weed like marine growth from the surface of the vessel that caused the increase in corrosion rate. It took an extra 4 years before the site settled down to its previous lower corrosion rate (MacLeod 2010b) (Fig. 4).

Over a 5-year period, a series of in situ conservation surveys were performed on a selected number of World War II Japanese wrecks located in Chuuk (Truk) Lagoon. The biodynamic relationship between the concretion thickness, the nature

of the colonizing organisms, and the concomitant effect on the underlying metal corrosion rate showed that the amount of light falling on a canted side of a shipwreck had a measurable effect on the extent of corrosion. The impact of the corals being the dominant sedentary epifauna on the sunny side meant that the branching nature of the corals causes localized increases in turbulence and hence corrosion rate (MacLeod et al. 2007). While the protective nature of the concretion cover is still beneficial, the changes in rugosity, or surface roughness, have a direct bearing on the corrosion mechanism and the intensity of the corrosion process. The differences in colonization result in systematic differences in the corrosion potentials and the pH of the iron underneath the concretion (Figs. 5 and 6).

In Situ Preservation of Shipwreck Artifacts, Fig. 6 The bow denuded of protective cover after an episode of "dynamite fishing" in 2004. (Photo: Bill Jeffery)

A previously undisturbed small fishing vessel was located in 2006 adjacent to a WWII dock on Tonoas Island and reported to the Chuukese authorities. The unnamed vessel, called the *Tonoas dock boat*, was used as a yardstick in the evaluation of the combined impacts of natural deconcretion events, due to typhoon damage, and the impact of "dynamite fishing" on the popular dive wrecks of the *Fujikawa Maru* and the *Susuki* patrol boat. Analysis of the concretion thickness on the *Susuki* patrol boat and the *Fujikawa Maru* showed that there were multiple layers of marine growth, with some areas having a series of up to five terraces representing marine concretion of varying ages on the *Fujikawa Maru*. While differences in the phosphorus content of the structural steels can account for some of the variations in thickness value t_{mm} of the concretion and corrosion matrix (MacLeod 1988), the most likely explanation is due to the impact of "dynamite fishing" which causes localized disbondment of the concretion as the explosion shock waves hit the surface (MacLeod et al. 2011).

When the *Fujikawa Maru* was originally inspected in 2002, it had a different corrosion mechanism to all other historic iron shipwrecks in that the slope of the Pourbaix or E_{corr} versus pH diagram was −0.059 V/pH instead of −0.028 ± 0.002 V/pH (Pourbaix 1974; MacLeod 2005). When the site was revisited in 2006, the corrosion mechanism had changed over to that of other iron wrecks. The initial relationship between E_{corr} and pH on the *Fujikawa Maru* is probably a reflection of the low stress microenvironment of the wreck, with its keel firmly supported by the seabed, whereas all the other wrecks were lying on their sides, upside down or on sloping substrates. Thus, the precise physical orientation of an iron shipwreck exerts a major influence on the way in which the vessel will corrode (MacLeod 2006).

The Impact of Explosions and Anchoring on Corrosion Rate

In order to determine the impact of human activities such as the use of explosives on wreck sites and the indiscriminate use of the wrecks as tie off points, the general Chuuk Lagoon corrosion equation (Eq. 4) was used to convert E_{corr} values from the *Tonoas* dock boat, the *Susuki* patrol boat, and the *Fujikawa Maru* into corrosion rates: the results are summarized in Table 1. When this information was meshed with local stories of when the wrecks had been last dynamited, it was possible to discern how long it takes before a wreck begins to recover from such events. Chuukese heritage professionals gave unofficial reports that the *Susuki* patrol boat was relatively undisturbed before the initial site inspection in 2002. Some time prior to the measurements in July 2006, there was a "deconcreting" event, but by the time the site was assessed, some recolonization of the wreck had taken place.

Around July or August 2006, a deconcreting event had taken place which caused an increase in the corrosion rate. In addition to the damage from "dynamite fishing," the *Susuki* patrol boat is also heavily impacted by novice divers during day- and nighttime visits since the dive supervisors regularly report that tourists break off corals as they adjust their buoyancy and try to hold on as they adjusted their buoyancy. By the time of the

In Situ Preservation of Shipwreck Artifacts, Table 1 Summary of observed and predicted corrosion rates for the three Chuuk shipwrecks

Wreck	Mean depth m	Mean depth graphitization mm	Calculated corrosion rate, mm/year	Observed rate mm/year	% corrosion rate over expected on depth
Fujikawa Maru	15.4	8.3 ± 2.4	0.098	0.143	46
Tonoas dock boat	14.4	5.0 ± 1.7	0.102	0.081	−20
Susuki patrol boat	7.2	10.0 ± 3.4	0.138	0.161	17

In Situ Preservation of Shipwreck Artifacts, Fig. 7 Collapse of the *Fujikawa Maru* bridge structure (August, 2007)

final set of measurements in August 2007, the site had begun to recover, and so the E_{corr} values had fallen from their dangerously high levels to somewhere approaching the original 2002 values. This oral history from the Chuukese staff shows that the wreck sites are in a dynamic equilibrium with the marine environment and that when damage occurs there can be relatively rapid recovery to pre-disturbance levels, but the continued practice of "dynamite fishing" results in permanent damage to the longevity of the wreck. The data from the three wrecks provides a direct comparison of the way in which the corrosion rate varies in response to the combination of damage from boat moorings, from divers breaking off the corals, and from the large impact of "dynamite fishing" on the corrosion rate (MacLeod et al. 2011) (Fig. 7).

The corrosion rate of the *Fujikawa Maru* is 46% above that calculated using the Chuuk shipwreck corrosion Eq. 4, while the *Susuki patrol boat* is 17% higher. Both of these vessels have suffered from increased corrosion as a result of multiple deconcretion episodes. The location of the *Fujikawa Maru* in the shipping channel results in a higher dissolved oxygen flux over the site which also leads to a great number of fish. This combination makes the *Fujikawa Maru* more prone to being hit by "dynamite fishing" activities than the more sheltered *Susuki* patrol boat site which has less abundant marine life. In addition the *Fujikawa Maru* is the most popular wreck site in the lagoon and is thus subjected to inadvertent diver damage. The damage to the concretion is consistent with physical impact of either shockwaves from dynamite fishing or from severe

tropical storms. It is likely that most of the dozen wrecks from which data had been collected had all been subjected to "dynamite fishing" events during their history since 1944. Because the general corrosion equation for Chuuk Lagoon was developed before the *Tonoas* dock boat site was found, the observed corrosion rate was 20% less than predicted.

The net effect of the episodic localized loss of this protective layer of marine concretion from the surface of the vessels is increased corrosion and loss of the underlying metal corrosion products which removes the archival record of the microenvironment and causes increased stress on the wrecks. Based on results from corrosion data collected in 2008, many of the wrecks in Chuuk Lagoon will begin to undergo significant collapse in the next 4–9 years. This has major implications for the management of the sites and for the safety of divers undertaking penetration dives. In addition, there is the risk of perforation of fuel bunkers on some vessels, possibly releasing petrochemicals into the fragile ecosystem potentially causing significant environmental damage in Chuuk Lagoon.

Impact of Intense Weather Events: The Case of Cyclone Yasi and the SS *Yongala* (1911)

A total of 122 passengers and crew perished in the wreck of SS *Yongala* (1911), and with the advent of charter boats and popularization through social media and diving networks, the wreck has become one of the top ten "must see" dive sites in the world. Until the introduction of proper mooring buoys, there was significant anchor damage to the protective concretion on the *Yongala* by more than 1,400 diving charters each year to the site which lies in the open waters of the Great Barrier Reef Marine Park off the Queensland coast (MacLeod and Viduka 2010). The heavily concreted shipwreck rests in 27–30 m of water, sitting approximately 14 m above the seafloor. The high physical profile of an intact iron steamship, warm tropical waters, and characteristic two-knot current that flows throughout the year have resulted in a veritable cornucopia of marine life. The initial assessment in 2005 was followed by intense wave action resulting from Cyclone *Larry* which partially deconcreted the stern in 2006 and exposed new holes in the remaining deck "plate." Three sets of in situ measurements were collected in 2007 which indicated that the wreck was beginning to recover from the impact of the previous cyclone. There was increased thickness of the concretion layers over previously damaged areas. Analysis of the corrosion potential, pH, and plate perforation data confirmed that the superstructure deck and hull plates are all highly corroded and that the most extensive corrosion is on the portside gunwale. The high corrosion rates found at the forward end of the forecastle deck and at the stern near the rudder are consistent with the exposed locations which lie proud of the seabed where there is significant water movement across the site (Fig. 8).

The naturally occurring cyclonic damage has resulted in accelerated corrosion of the wreck in much the same fashion as the "dynamite fishing" in Chuuk has accelerated the decay of the Japanese WWII shipwrecks. The 2007 data showed that the *Yongala* bow was corroding at a higher rate than the stern and that its unsupported nature placed increased stress on the hull and this manifested itself in increased corrosion on the residual metal structure. Changes in the souring have also been significant factors in accelerating the corrosion of this historically significant iron shipwreck. The impact of a second cyclone was dramatic when cyclone *Yasi* hit Queensland coastal communities and hinterland in February 2011. Although the center of the intense cyclone was hundreds of kilometers north of the site, deep ocean waves wrenched massive amounts of concretion from the wreck, and the bow has collapsed and dropped several meters to rest on the seabed. The *Yongala* moved from about 60° before the storm to 80° from the vertical, after the extreme weather event. The concreted hull plates have collapsed in sections and this has opened up the interior of the wreck to direct action of the prevailing currents. Without direct intervention and active site management, the wreck will now undergo a relatively dramatic change in its physical form as elements begin to become disconnected and move across the site. The lesson from the in situ corrosion studies on the *Yongala* is that

In Situ Preservation of Shipwreck Artifacts, Fig. 8 *Yongala* bow after the impact of cyclone Yasi. (Photo: Museum of Tropical Queensland)

such data can lead to the development of predictive models of site collapse that can also be reverse engineered into determining the likely causes of wreck formation processes on other historic shipwrecks.

Sacrificial Anodes and Artifact Stabilization

Although the successful in situ treatment of historic shipwreck cannon and anchors, marine engines, and even the remarkable steam-driven submarine *Resurgam* has been reported by Gregory and MacLeod (Gregory 1999, 2000; MacLeod 1992, 1996), some elements of the shipwreck community remain skeptical about the efficacy or efficiency of such processes. Conservators and maritime archaeologists need a method of determining how an in situ treatment is progressing and when it will be finished. Recent work by the author has shown that the Cartesian (arithmetic) product of the pH and corrosion potential is dependent on the burial environment. This data provides a special insight into the state of decay of the objects since all aerobically corroded iron artifacts have a common value when the two in situ parameters are multiplied together. The wreck of the *Swan* (1653) at Duart Point, Isle of Mull, Scotland, is instructive as the site has seen the successful application of anodes to several cannon after the pre-disturbance corrosion survey was conducted. When the treatment data is plotted on a Pourbaix diagram, all the guns had a common slope with an average value of −0.087 V/pH which is consistent with the following corrosion reaction taking place, during the treatment phase, viz.,

$$Fe + 2H_2O \rightarrow HFeO_2^- + 3H^+ + 2e^- \qquad (6)$$

Equation 6 has a predicted slope of $-{}^3/_2{}^*0.0568$ or −0.085 V/pH at a seawater temperature of 13 °C. The data strongly suggests that the underlying passive corrosion process produces the hydrogen ferrate ion $HFeO_2-$ and not the normal ferrous ions associated with corrosion in the absence of anodes. The corrosion process is no longer controlled by the oxidation of iron to produce $FeCl^+$ species (Man-Seung 2004) but the underlying corrosion process is the very slow oxidation of iron under alkaline conditions. In other words, the monitoring of the in situ corrosion parameters has shown that the iron is in a passive state, the desired outcome of all conservation treatments (Fig. 9).

Determining the End Point of an In Situ Treatment

Analysis of data from pre-disturbance surveys on iron artifacts indicates that the common solution microenvironment underneath the concretion consists of $FeCl^+$ in equilibrium with a small

In Situ Preservation of Shipwreck Artifacts, Fig. 9 Diver attaching a zinc anode to a cannon on the *Swan* wreck site, Sound of Mull, Scotland. (Photo: Colin Martin)

percentage of $FeCl_2$ and a trace of $FeOH^+$ (Man-Seung 2004). For the convenience of discussion, the Cartesian product of the pH and E_{corr} can be described as a "corrosion indicator" (CI) which has a median pre-disturbance value of -3.6 ± 0.4 from wreck sites which range from the wreck of the *Swan* in 1653 through the USS *Monitor* (1862) turret, the hull of the Civil War submarine *H. L. Hunley* (1864), to the anchors and cannon from the HMS *Sirius* (1770), and the hull plates of the *City of Launceston* wrecked in 1865 in Port Phillip Bay, Victoria, Australia (MacLeod 2010b). The site variables such as temperature, the dissolved oxygen content, and the salinity all impact on the pH and E_{corr} values, but these factors essentially cancel out each other to provide the basis for a common value which simply reflects the common corrosion mechanism. By monitoring the E_{corr} and pH through routine visits to the wreck sites, the CI value of artifacts undergoing treatment can be determined. A detailed discussion of how the end point of the treatment value for the corrosion indicator was developed has been previously reported (MacLeod 2013), but when the end point CI value of -7.3 ± 0.2 is reached, the bulk of the chlorides have been removed from the object, the surface pH has become more alkaline than the surrounding seawater, and the overall corrosion rate has fallen to quite low values. One impact of the knowledge of the end point for in situ treatment of iron artifacts is that it became apparent that the *Cerberus* gun barrels were completed after approximately 3 years of stabilization with zinc anodes. The short treatment time is due to the fact that they had only been exposed to general marine atmospheric corrosion while located in their twin turrets on the 1870s built Monitor-style warship (MacLeod and Steyne 2011).

Artifacts corroding in a buried or partly buried marine microenvironment have a different corrosion mechanism to those objects lying proud of the seabed. Under low-oxygen or anaerobic conditions, the principal corrosion product is magnetite Fe_3O_4 and the cathodic process involves reduction of either hydrogen or water. The different mechanism is reflected in different pre-disturbance values of the corrosion indicator. Examples of this type of microenvironment are found for the wrecks of the Australian WWI submarine HMAS *AE2* (1915) in the Sea of Marmara and the submarine *Resurgam* (1880) off the coast of North Wales where the median CI value for the two submarines was -4.6 ± 0.1, which is typical for a partly stabilized aerobically corroded iron artifact (Gregory 2000; MacLeod 2010b). Although the SS *Xantho* was periodically buried and exposed, all the pre-disturbance values relate to the extended aerobic microenvironment with a CI value of -3.3 for the historic Penn of Greenwich engine (MacLeod 1986; McCarthy 1988). The value of the product of E_{corr} and pH changes during in situ conservation treatment with sacrificial anodes and reaches a minimum at which point the treatment is completed, i.e., the end point. Treatment times vary according to the water depth and are more rapid on shallower sites and shorter for more extensively corroded artifacts.

The model was developed using data from the corroded guns on the wrecks of the pinnace *Swan* (1653), the Monitor-styled warship HMVS *Cerberus* (1926), and a series of wrecks in Australia and the United States of America (MacLeod 2013).

Treatment Kinetics for Cannon on the *Swan* (1653)

Data collected by Gregory and MacLeod on the *Swan* wreck site has been of significant value in determining the factors that control the rate at which the artifacts are going to be treated by the anodes (Gregory 1999; MacLeod 2013). Because the efficacy of anodes depends on the ratio of the surface area of the object to the anode, changes in the pH and E_{corr} values during treatment cannot normally be compared owing to the different surface area of object to anode ratios used on different sites. Since all the anodes used on the cannon on the *Swan* had very similar surface area ratios, the data from the changing values of the corrosion indicator provided some useful clues to the overall kinetics of the treatment process. As electrons flow into the cannon and anchors, the unbound hydrogen ions are reduced to hydrogen gas, with a concomitant increase in the pH. The cannon showed a linear increase in pH with time, and the slopes of the pH versus time plots are dependent on the d_g values or the annualized long-term corrosion rate according to Eq. 7:

$$\partial pH/\partial t = 4.47\, d_g - 0.007 \qquad (7)$$

The linear regression for Eq. 7 had an R^2 of 0.9315, and the standard error associated with the slope was ±0.54 (12%) and the intercept error was ±0.086. When the E_{corr} data from the *Swan* was combined with the pH during treatment, it was found that the corrosion indicator value became increasingly negative as time increased according to Eq. 8:

$$CI_{Duart} = -3.35 - 0.72\, t \qquad (8)$$

where t is the treatment time in years and the R^2 value of 0.9602 was associated with the linear regression equation number eight which shows a very good correlation of the data. If the amount of time for completing the in situ conservation of the object(s) is required, then substitution of the end CI value of 7.4 into the above equation gave a predicted treatment time of 5.65 years. Thus, through periodic measurements of the normal in situ corrosion parameters, it is possible to determine the percentage of the conservation program that has been achieved by the artifact(s). Since the predicted treatment time for the guns and anchor at the *Swan* wreck site is now well past, the in situ conservation treatment will have been completed, and the site kept in a state of suspended animation until there is a compelling need for additional excavation and a home for the conserved artifacts are established as part of a properly curated exhibition in a venue that fits for the purpose. The archaeological director reports that the anodes are now corroding away at a much reduced rate which also supports the understanding that the conservation process has been completed (C.J.M. Martin, *pers. comm*. 2011).

Similar analyses of data on the speed at which the corrosion indicator moved toward the end value of -7.4 ± 0.3 were conducted for the *Sirius*, *Xantho*, and *Cerberus* sites and showed that the corrosion indicator moved faster toward the completion value as the depth (d) became shallower in accordance with Eq. 9:

$$\partial CI.y^{-1}/\partial d = -1.39 + 0.18\, d \qquad (9)$$

This relationship means that in situ conservation treatments will work fastest at shallower depths since increased wave action, brought about by wind driven events, will increase the flux of dissolved oxygen to the corroding anodes and make them work more efficiently. This relationship enables conservators, site managers, and maritime archaeologists to predict how fast the artifacts can be treated based on the water depth in meters.

Methodologies for In Situ Preservation of Organic Materials

One critical factor in modelling the preservation of objects from an archaeological site is the applicability of data recovered from post-burial

environments of model artifacts. It is a problem common to all of corrosion and archaeological sciences, but so long as data is compared with other appropriate subsets from a similar microenvironment, then the conclusions drawn have a reasonable chance of being valid. Although the literature abounds in numerous reports of such activities, the work at the National Museum of Denmark and at the Western Australian Maritime Museum are instructive and complement the data from the Marstrand Reburial and Analyses of Archaeological Materials (RAAR) project in Sweden as they are all pointing practitioners down on more sustainable paths.

The concept of reburial of ship timbers in the marine environment was established by the Dutch pioneer De Jong and by Kirsten Jespersen in Denmark, but the effectiveness of the methodology was not fully developed, so the impact of the reburial on archaeological timbers was poorly characterized. This lack of detailed understanding was overcome by Gregory as he developed a methodology using standard modern oak and a cellulose-based canvas as means of assessing deterioration in the first stages of decay. If the initial rapid decay of artifacts can be effectively modelled and understood, it makes the task of predicting the long-term future much more attainable. Since most degradation mechanisms by molds, fungi, wood-boring molluscs involve the organisms respiring in an oxygenated environment, the first samples were located at the oxygenated seawater interface, the next cohort just below the surface at a depth of a few centimeters and below 50 cm to gauge the change in mechanism of going to a completely anaerobic microenvironment. His work pointed out the many pitfalls of attempting to interpret short-term field experiments on standardized timber coupons, but it did show that the least degradation was obtained on samples buried deeper than the 50 cm layer of sediment (Gregory 1998). The impetus for the determination of the optimum reburial microenvironment for the National Museum of Denmark was the presence of more than 5,000 Iron Age wooden artifacts in a waterlogged meadow site, Nydam Mose, located in Southern Jutland, Denmark. To treat all of these materials was questionable in terms of the capital and maintenance costs of the collection and the fact that when left undisturbed and maintained in a stable anoxic aqueous microenvironment, the timber artifacts appeared to have excellent preservation. Monitoring the dissolved oxygen levels, the redox potential, and the quantities of salts has provided good insights into the major role of erosion bacteria in controlling the biodeterioration of the waterlogged organic remains and of the importance of maintenance of the water table (Gregory et al. 2001). Recent work in England on finding the correct turning point for burial depth of organic remains indicates that depths in excess of 2 m may be required to ensure that the overall rate of all bacterial attack, both aerobic and anaerobic, on the structural components of the wood is at a minimum (Hogan et al. 2001).

The shipwreck *James Matthews* (1841) in Cockburn Sound near Fremantle had for many years been in a stable burial environment under at least a meter of sand, but it was being subjected to a combination of natural erosion and increased industrial activity, since it is located next to a retrieval jetty for harvesting dumped shell materials for a local cement works. The systematic approach shown by Richards and her team in establishing the pre-disturbance conditions for the microbiological, electrochemical, and physical oceanography of the site shows the depth of knowledge that is needed before informed decisions can be taken on the efficacy of reburial in situ conservation plans (Godfrey et al. 2005). The wreck has been able to be stabilized through the use of sediment-filled road crash barriers, covered with geotextile to minimize loss of sediment during storm surge (Winton and Richards 2005). A long-term approach to monitoring the efficacy of interventions on a wreck site has proven to be very useful in that data collected over a period of more than 5 years has shown the complex relationships between the natural balance of microbiological populations and a variety of wood-boring molluscs and marine fungi (Fig. 10).

Richards work on assessment of changes wrought by various interventions is highly regarded for its direct relevance since samples of the ships timbers were able to be taken for

In Situ Preservation of Shipwreck Artifacts, Fig. 10 In situ assessment of hull timbers on the *James Matthews* (1841) wreck. (Photo: Jon Carpenter)

destructive analysis rather than using modern test specimens of timbers pertaining to the period of construction of the vessel which had only been exposed for a few years. Through direct engagement with the maritime archaeological site manager, a unique insight into site degradation and formation processes has been able to be developed. It is only through all the data from sediment cores, microbiological assays, analysis of the wood degradation mechanisms, and the microelectrodes that quantified the variations in dissolved oxygen and redox potentials that the total picture can be obtained. Richards clearly established that canvas-based sandbags were useless and that the partially filled synthetic sandbags need to be carefully chosen for the stability of the parent polymer, but they were nevertheless useful in providing temporary protection of the site. The additional data gathered after the initial study into the use of road crash barriers strongly supports this form of site stabilization. It is important to remember how to weigh up initial capital cost with the outcome which is the preservation of a unique historic wooden sailing vessel that once took African slaves to the plantations in the Americas (Richards et al. 2009).

Following industrial pressures of seabed dredging to improve harbor and ferry access through a series of archipelagic channels which would profoundly affect a series of shipwreck sites, the Marstrand reburial project was born in which it was bravely heralded that the research design would be transgenerational in that 50 years of data would be needed to fully ascertain the efficacy of the proposed methods of in situ stabilization. The findings of the first 3-year analysis of the data indicate, somewhat surprisingly, that reburial is not a good option for glass and fibrous materials but indications are that it is an option for some metals and inorganic matrices such as porcelain, stoneware, and clay pipes as well as for wood (Nystrom et al. 2009). The RAAR project has already achieved some significant milestones in that it has demonstrated the viability of collecting localized microenvironment physical chemical parameters of dissolved oxygen, pH, and redox potentials in that they provide comparable data with that obtained from fixed data loggers operating underwater in situ. The data has also produced a very sound set of guidelines about the precise location and positioning of samples of different types of materials found on historic shipwrecks, but in this instance simulated by modern coupons made from representative alloys or wood samples. Although funding for the continuation of the project is somewhat problematic, the data already reported is of considerable value as it points out all the pitfalls of reburial projects which are of immense assistance to heritage managers in determining which artifacts should be recovered and conserved (Nyström Godfrey 2009).

İnan, Jale

Ece Birçek
Istanbul, Turkey

Basic Biographical Information

Jale İnan was born in 1914 in İstanbul. Her father, Aziz Ongan, who was one of the very first archaeologists born in Turkey, was the cofounder and a long-term director of the İzmir Archaeology Museum. After her graduation from Erenköy High School for Girls in 1934, with a scholarship from the Alexander Von Humbolt Foundation,

Jale İnan went to Berlin, Germany, to study archaeology. A year later, she was awarded the Turkish Republic Scholarship and overcame severe hardships during World War II to complete her undergraduate education. Under Prof. Dr. Rodenwalt's supervision, she finished her Ph.D. dissertation entitled *Art Historical Study of The Sacrificial Action on Roman Coins*. Inan returned to Turkey in 1934 and before the Classical Archaeology Department was established, she began to assist Prof. Dr. C. Bosch in the Ancient History Department.

The Classical Archaeology Department was formed in 1946 and Jale İnan became Arif Müfid Mansel's assistant. Along him, she helped to build the new department and establish a tradition of excellence. She was promoted as associate professor in 1953 and as professor in1963. Inan become the head of the Classical Archaeology Department in 1975 and retained status quo until her retirement in 1983.

Major Accomplishments

Since 1946, Jale İnan participated in the excavations of Side and Perge led by Arif Müfid Mansel where she served as vice director. Afterward she took charge of excavations at Side between 1974 and 1980 and Perge from 1974 to 1980. She also carried out salvage excavations in ancient sites as Kremna and Pamphylia Seleukeia (1970–1979). Inan also chaired the excavation and restoration studies in the Temple of Apollo, Side. In addition, she played a major role in the repair and restoration of Side's Roman bath construction as a representative museum. She wrote numerous significant articles and books on the art of ancient sculpture.

Jale İnan's publications filled in major gaps in the study of Roman and Early Byzantine portraiture and are important reference sources. Her research in Europe resulted in identification of the fragments of statues from Side/Perge ancient sites and was integral in having them brought to Turkey and restored and displayed.

Inca State and Empire Formation

R. Alan Covey
Department of Anthropology, Dartmouth College, Hanover, NH, USA

Introduction

In 1532, when Francisco Pizarro's rag-tag band of conquistadors captured and executed Atahuallpa, the last independent Inca emperor was overlord of the largest native civilization to develop in the Americas (Fig. 1). Although Atahuallpa had recently turned the might of the Inca military machine away from a grueling expansion campaign on the northern frontier to contend with his half brother, Huascar, for the imperial title,

Inca State and Empire Formation, Fig. 1 Map of Inca territory at the time of the European invasion

the Incas were still in the process of territorial expansion and provincial consolidation when the foreign invasion interrupted their dynasty. Tawantinsuyu, the Inca "Realm of the Four Quarters," had a population comparable to that of Spain at the time, one that spoke dozens of languages and dialects and lived across some of the planet's most diverse landscapes. The conquering Spaniards did not stop to ponder what factors enabled Inca imperial unity, or to reflect on the rapidity of the Inca military achievement (much of the empire's territory had been annexed in the lifetimes of the oldest living informants). A generation later, the chronicler Juan de Betanzos recalled (1996[1550s]: 3) that the Spaniards "paid less attention to fact finding than to subduing and acquiring the land and... because they were unaccustomed to dealing with the Indians... they did not know how to make inquiries and ask questions because they lacked an understanding of the language. Moreover, the Indians were afraid to give them a full account."

Definition

The question of Inca origins is saturated with ideologies of imperial self-justification found among Incas and Spaniards in the late sixteenth and early seventeenth centuries. Inca informants and Spanish writers alike sought to colonize the past to promote their own immediate interests – to see the rise of the Incas as the realization of the ideals of civilization, or as a descent into tyranny and demonically inspired depravity. Although archaeology is constrained by its own incompleteness and bias, recent decades of research have established independent evidence of the remains of the Andean world at the time of Inca origins. Today, Inca scholars are in a position to offer a much more solid narrative on the origins of this impressive society.

The Incas were not the first Andean civilization, but their state formed during uncertain times, when many Andean societies had turned away from political hierarchies and central institutions. As climatic conditions fluctuated around CE 1000, most highlanders focused on social networks that could labor across a diverse set of resources, and they defended their homes, pastures, and fields from local rivals as populations grew to strain resource availability. Rather than manage risk through diversity, the Incas and a few of their neighbors focused on surplus production, and as populations grew their leaders organized the construction of new irrigation canals and agricultural terraces to cultivate maize and other crops. Inca society eventually grew to be larger and more hierarchical than its neighbors, and its leaders began to establish formal ties to groups across the Cuzco region, relationships that brought labor tribute and turned the growing city of Cuzco into a ceremonial center where labor was reciprocated through rituals and festivities. Whereas marriage allies augmented labor available for royal projects, Inca enemies became targets for conquest, and a century or more saw Inca armies reduce many groups to tributary status, opening up new lands for intensification and royal estate construction. The Incas raided their most powerful rivals for generations before finally conquering them on the eve of the first imperial campaigns.

By CE 1400, the Inca ruler was the most powerful lord in the central highlands, and the state controlled a large population that provided labor on improved farmlands to produce massive surpluses for state functions and religious offerings and to supply large armies on extended campaigns. A state conquest ideology would have been necessary to justify imperial entanglements beyond the Cuzco region, and the ruler who wished to lead Inca armies beyond traditional boundaries would need charisma and political savvy to encourage Inca nobles and commoners to labor harder and risk their lives to support expansion. Undoubtedly, this is where stories of external threats, challenges to the Inca paramount title, and assertions of divine patronage would have been influential, but these claims alone were not sufficient to launch the juggernaut of empire.

Historical Background

The Spanish crown only began to address the question of Inca origins seriously in the 1550s, as part of a debate over whether military conquests in the Americas were just (Covey 2006a). To collect narratives of the Inca past, chroniclers turned to indigenous informants, including members of royal Inca lineages who provided particularly detailed narratives of their ancestors' feats. The Incas did not preserve their histories in writing prior to the European invasion; instead, they relied on the memories of oral history specialists – who were aided by the *khipu*, a collection of knotted cords that could be used to record some information – as well as periodic ceremonial performances that celebrated a ruler's conquests. Private histories of the Inca nobility served as the basis for "official" state accounts that periodically purged and reorganized the master narrative. Inca elites approached the transcription of Spanish accounts of their dynasty as a comparable project, one that offered a means of solidifying their status on the emerging colonial landscape.

The corpus of colonial Inca sources is a complex collection of archival documents and published chronicles that can be divided roughly

into four principal periods (Table 1). It is important to recognize that many sources available for study today were not published until the nineteenth or twentieth century. Eyewitness accounts written before 1550 generally show limited regard for Inca history, emphasizing the military exploits of Spaniards during the conquest and subsequent civil wars of the 1540s and early 1550s. Spaniards wrote the first detailed narratives of the Inca dynasty in the 1550s (e.g., Betanzos, Pedro de Cieza de León, Bartolomé de Las Casas), but these were generally not published at that time. By the 1560s, the Spanish crown began to assert control over publications about the Inca past, decreeing that a royal chronicler be sent all manuscripts so that an official account could be kept. The creation of an "official" Inca chronicle – the unpublished 1572 account of Pedro Sarmiento de Gamboa – and censorship of other sources established Spanish royal control over the Inca past, which only relaxed after the death of Philip II in 1598. The first indigenous accounts of the Inca past were written in the early seventeenth century, and some of the earliest manuscripts finally found their way into publication in secondary sources that excerpted them, often without attribution. Few scholars consider materials produced after the 1650s to be part of the body of primary documents.

Considering the diverse corpus of Inca chronicles and the different contexts under which different sources were written, the discussion of Inca origins requires attention to a number of interrelated questions that colonial documents and archaeological data address in different ways. Early colonial writers were most concerned with understanding when "civilization" and "good government" were first established in the Andes, and with establishing how far back into the past the Inca dynasty could be credited with imperial conquests. This entry addresses these highly political colonial-era themes in light of a large body of archaeological data collected in recent decades.

Inca State and Empire Formation, Table 1 Key periods of Inca historiography (dates approximate)

Dates	Sources
1532–1550	Eyewitness accounts
1550–1565	Early dynastic histories
1565–1600	Crown-controlled histories
1600–1650	Indigenous and secondary accounts

Key Issues/Current Debates

The Incas claimed to be the first and only civilization to develop in the Andes. After the time of creation, the first ancestors emerged onto the wild landscapes of the region, taming them and establishing the trappings of human life. Indigenous chroniclers recount that the land eventually became overpopulated, leading people to abandon good farmland and seek mountaintop fortresses as conditions of universal warfare descended on the Andean world – Felipe Guaman Poma de Ayala (2009[1615]) called this time "The Age of the Enemy" (*aucapacha*) (Fig. 2). Inca order brought

Inca State and Empire Formation, Fig. 2 Guaman Poma de Ayala's depiction of universal warfare before the Incas established the first and only Andean civilization

the fighting to an end, establishing civilized government and permitting people to return to the places that their ancestors had selected to settle.

Archaeologists have known for more than a century that the material record contradicts the indigenous Andean account of the rise of civilization. Excavation work on the Pacific coast and in the highlands has identified urban centers that predate the Incas by centuries, and archaeological data offer detailed reconstructions of earlier states, such as Moche and Chimú on the coast, and Wari and Tiwanaku in the highlands. Because Inca expansion was so rapid and subsumed the core territories of all states that came earlier, some scholars have pondered the extent to which the Incas inherited or appropriated the institutions of their predecessors. The emergence of the Inca dynasty as a leading power in the Cuzco region followed a period of more than 200 years of balkanization after the disintegration of the Wari and Tiwanaku states. Although the Incas may have retained some practices regarding labor coordination and agricultural intensification that Wari colonists brought to the Cuzco region from CE 600 to 1000, Inca religion, economy, and state infrastructure are different in many ways from the practices of earlier states.

Despite recognizing the flaws in the indigenous story of creation cycles and the rise of Inca civilization, archaeologists have often invoked the Andean concept of universal warfare when describing the archaeological evidence from the central highlands after CE 1000. With the onset of more arid and fluctuating climatic conditions around that time, most highland populations abandoned intensive agricultural practices in favor of mixed farming and herding. Local economies emphasized kin-based production of diverse resources as a principal risk management mechanism, and many communities settled in locations offering maximum local environmental diversity, as well as natural defenses against predation of the resources needed to survive. Many highland regions saw a shift to hilltops and ridges, with settlement hierarchies indicating an absence of centralized political administration. Population growth from CE 1000 to 1200 in many parts of the highlands attests to the adaptive success of this new economic regime, but extensive subsistence practices required large catchment areas, and some societies became victims of their own successes – increased conflict marked the final years before Inca conquest. Radiocarbon dates suggest that warfare escalated in frequency and scale in many regions after CE 1200 or so, and fortifications (*pucaras*) are common across the central highlands during this time. Thus, indigenous chroniclers such as Guaman Poma de Ayala are correct that the Inca empire emerged on a densely populated, decentralized highland landscape that was plagued by frequent raiding and warfare; but these were the long-term results of successful social adaptations tied to the collapse of earlier states, rather than the progression from a natural condition to a civilized one. It is noteworthy that the Cuzco Valley and some nearby areas represent a rare exception to the *aucapacha* model – the most powerful groups in the region lived in large valley-bottom settlements in close proximity to fertile maize lands.

The general trends in highland settlement patterns in the Late Intermediate Period – diversity-oriented economies, defensive settlements, and regional decentralization – offer a context for considering Inca accounts of their ancestral origins. Inca nobles claimed that their ancestors had been present for universal creation, making particular links to the celebration of regional pilgrimages in the Lake Titicaca region (Bauer and Stanish 2001). At a more local level, they claimed that the ancestral male–female pairs who founded their dynasty had emerged from a cave in a place called Pacarictambo, located to the south of the Cuzco Valley (Bauer 1992) (Fig. 3). The Inca ancestors journeyed northward in search of fertile maize lands where they could settle, conquering local groups and establishing shrines along their route. It is said that Manco Capac, the first king, knew to settle in Cuzco when a golden staff that he carried sank into the deep soil of the valley (Sarmiento de Gamboa 2007[1572]: Chap. 13). Indigenous accounts of the first Inca (e.g., Garcilaso de la Vega 1966[1609]: Book I, Chap. 18) identify prominent counterparts – other rulers with the kingly title "capac" – living to the northwest and southeast of the Cuzco Basin.

Inca State and Empire Formation, Fig. 3 The rock of Poma Orqo, celebrated in imperial times as the place of emergence of the first Inca royal ancestors

Inca State and Empire Formation, Fig. 4 Important settlements of Late Intermediate Period (CE 1000–1400) Cuzco. The Incas and their most powerful rivals were valley-bottom farmers living in large communities

Although the Inca ancestral origin story contradicts key archaeological facts, it preserves some important truths that are borne out in the settlement pattern data. The Incas were valley-bottom maize farmers, as were their most powerful early rivals. As Fig. 4 shows, there is an axis of large valley-bottom settlements occupying some maize-producing areas in the Cuzco region, which includes the Cuzco Basin and the areas where Inca myths identify rival kings. These communities lack evidence of defensive works and suggest that surplus maize production was a key risk

management strategy. This subsistence pattern is virtually nonexistent elsewhere in the Andean highlands at this time.

International Perspectives

Inca narratives of imperial origins present a paradoxical stance regarding threats from rival polities – on the one hand, the Incas claimed to be the only Andean civilization; but on the other hand, they justified the expansion of their empire as a strategy for defending themselves from the imperialistic designs of rival groups. Just as archaeologists have been willing to build interpretive models around the flawed account of universal warfare in the pre-Inca Andes, many have accepted the Inca claim of defensive imperialism, which was allegedly catalyzed by the invasion of the Cuzco region by Chanca armies in the early fifteenth century. Viewing Inca imperial origins as the outcome of a single battle lends itself to a historicist reading of Inca imperial origins, where a single charismatic ruler named Pachacutic Inca Yupanqui repelled the invading Chancas and then proceeded single-handedly, and without precedent, to create imperial institutions and to lead campaigns of conquest.

This interpretation of Inca origins owes much to the pioneering work of John H. Rowe (e.g., 1945), who identified Pachacutic as the Inca who founded the empire and who established a dynasty whose exploits can be largely treated as historical. Rowe accentuated the historicity of the imperial Inca rulers – Pachacutic, Tupa Inca Yupanqui, Huayna Capac, Huascar, and Atahuallpa – by promoting calendar dates from the 1586 chronicle of Miguel Cabello Balboa (a source that is otherwise largely ignored for its content). The year 1438, said to be the accession of Pachacutic, came to mark the sudden florescence of the Incas as an imperial society – and their emergence from the shadows of legend into the historical realm.

Although archaeological data are better suited to addressing processes than historical events, recent research in the Andean highlands has revealed the Inca claim of defensive imperialism to be a chimera, invented as part of the imperial conquest ideology. The homelands of the groups said to have threatened the existence of Inca society have been found to be far less powerful than described in the sixteenth century. Regional settlement patterns in the Chanca homeland exhibit defensive settlement and regional decentralization that are common across most parts of the Andean highlands during the Late Intermediate Period (Bauer et al. 2010). The same is true for the Colla region of the Titicaca Basin – although Inca informants claimed that their early campaigns there were motivated by the imperial designs of the Colla ruler, their descriptions of expansionist kingdoms are utterly at odds with the archaeological evidence (Arkush 2011).

Rowe's historicist paradigm was based on the writings of early colonial Spanish writers who thought about history in terms of dynastic lists and who approached the question of Inca imperial origins by asking which king created the empire and led the Incas out of Cuzco on their first imperial campaigns. Explaining the unprecedented and meteoric rise of a great man led many writers to invoke supernatural explanations that modern scholars would not take at face value. For example, Pachacutic won his victory over Chanca invaders not as a general commanding Inca troops, but with the aid of an army of fieldstones that were transformed into human warriors and armed by the creator, Viracocha, who had appeared to the young Inca prince before the battle to promise him victory and imperial success. Today, many scholars emphasize a sudden flourish of Inca imperial power under Pachacutic, but they downplay the acts of divine intervention that the colonial sources employ to explain that transformation.

Contrasting with writers who were preoccupied with a single great man, the early colonial jurist Polo de Ondegardo framed the issue in terms of social transformations and changes in the balance of power in the Cuzco region. To answer how the Incas had conquered the Andean region in just a few generations, he wrote in 1571 (1916: 51) that "these Incas conquered through violence and warfare. . . and thus the only difficulty was in conquering those neighboring polities of the Cuzco region, because afterwards, all the

conquered groups went with them [the Incas], and it was always a much larger force than the others [i.e., opposing local groups]." If the key to Inca success was the conquest and consolidation of the Cuzco region, many chronicles fall short of explaining these processes. Indigenous chronicles claim that Manco Capac, the founder of the Inca dynasty, unified the Cuzco region under Inca ruler during his lifetime, allowing the Incas to expand as an empire from the earliest generations. This claim cannot be reconciled with the archaeology of the Andes in the centuries before the Spanish conquest, a fact that motivated Rowe to propose a later origin for the empire. The chronicles that describe imperial origins through the heroic accounts of Pachacutic (or his father, Viracocha Inca) focus on supernatural forces instead of social power, also falling short of a convincing explanation. In recent decades, new archaeological data and a process-based reading of the chronicles have developed a more nuanced sense of the processes of Inca state formation and the development of the institutions and strategies that enabled rapid imperial expansion.

Multiple Inca dynastic narratives describe how the Incas came to dominate the Cuzco region during the three or four generations before the first imperial campaigns. By studying Inca state formation as a long-term process affecting the Cuzco Valley and neighboring areas, the documentary record can be studied alongside the regional archaeological database, which offers coarse-grained perspectives on settlement pattern changes before and after Inca conquest (Bauer and Covey 2002; Covey 2006b). The chronicles describe several important ways that Inca society changed in the generations leading up to territorial expansion beyond the Cuzco region. Among these are royal marriage alliances, intensification of agricultural production, and military conquest. Whereas the first three or four Incas took their principal wives from villages in the Cuzco Basin, the generations that followed made strategic alliances with groups living in the surrounding region. These marriages consolidated the labor tribute owed to the ruler and his wife (or wives), which royals invested in new agricultural canals and terraces that they passed on to their descendants. The earliest known royal estate resources are found in the Cuzco Basin, but military conquests in the surrounding region brought new development opportunities in the neighboring Vilcanota-Urubamba Valley, where at least six generations of Inca rulers established valley-bottom maize lands (Covey 2006b). The chronicles describe military engagements developing into logistically sophisticated campaigns that conquered multiple holdout communities and reduced them to tributary service.

The archaeological evidence from Late Intermediate Period Cuzco augments documentary perspectives on Inca social transformation. Pre-Inca settlement patterns include scattered high-elevation villages like those seen across most of the highlands from CE 1000 to 1400, especially to the north and south of the Cuzco Valley (Bauer 1992; Covey 2006b). The Inca impact on these regions varied. To the south, the royal celebration of the Pacarictambo origin myth led to the construction of a new installation at Maukallaqta, associated with the Poma Orqo rock outcrop and the places mentioned in the ancestral migration to Cuzco. Despite the royal promotion of this new pilgrimage route, local settlement patterns remained largely unchanged, with existing villages simply connected by roads. In the Sacred Valley to the north of Cuzco, however, major resettlement occurred as the focus of population shifted from mountains and ridgetops to country palaces and scattered small settlements located around new valley-bottom fields built by royal lineages. Royal estate construction in the Sacred Valley began after the conquest of local populations, which is said to have occurred prior to the first imperial campaigns.

Contrasting with the highland pattern of decentralized and defensive settlement, the Cuzco Basin and areas to the east and west constitute an axis of large valley-bottom settlements located near fertile maize lands. Settlement in these areas was more nucleated and hierarchical, and presumably focused on surplus agricultural production on improved farmlands. The Inca impact across these areas was not uniform. Some areas show evidence of widespread site abandonment, such as the Maras area to the northwest of

Cuzco, where the settlements of a significant Inca rival were replaced by facilities associated with royal estates. In other parts, such as the area around the town of Anta, where honorary Inca groups lived, large villages exhibit settlement continuity from the first millennium BCE through the Inca period. A third pattern of valley-bottom occupation involved resettlement of areas lying between Inca territory and the lands of powerful rivals, which were presumably too dangerous to occupy and farm during conflicts with neighboring groups. This has been observed in the Oropesa Basin to the southeast of Cuzco (Bauer and Covey 2002).

Future Directions

Together, the chronicles and archaeology describe Inca origins as a regional process that affected Cuzco's different groups to varying degrees. A centralized state government was established in the Cuzco Basin well over a century before the first imperial campaigns, and the combination of marriage alliances, military campaigns, royal intensification projects, and resettlement of local populations increased the population providing labor service to Inca rulers, while also honing military tactics and ideological justifications for conquest warfare and subsequent economic intensification. The final consolidation of Inca rule over the Cuzco region coincided with the first imperial campaigns around CE 1400.

Although much progress has been made toward reconciling the documentary and archaeological records from the Cuzco region, there are still important avenues for future research to clarify aspects of Inca origins. Cutting-edge climate science in the south-central Andean highlands is reconstructing the environmental conditions under which the maize-farming Incas expanded into the lands of their neighbors, and modeling settlement pattern shifts with changing environmental conditions is a significant interdisciplinary task that lies ahead. Archaeological data are scarce in the areas lying immediately beyond the Inca imperial heartland, making it difficult to reconstruct and date the degree to which the conquest of the Cuzco region corresponds to the timing of the first imperial expansion campaigns. Finally, there is much to be learned about daily life in the Cuzco region before and after Inca unification of the region, and more domestic excavations are necessary to understand the true impacts of Inca rule on everyday life.

India: Historical Archaeology

Barry Lewis
Department of Anthropology, University of Illinois at Urbana-Champaign, Urbana, IL, USA

Introduction

The roots of Indian historical archaeology rest in late eighteenth and early nineteenth century antiquarian research, a collaborative enterprise driven mostly by questions of historical interest for which archaeological evidence played an important role. The results of these investigations brought India's rich history, ancient and diverse literary traditions, and spectacular archaeological sites and monuments onto the world stage. They also gave India's colonial government its main rationale for direct involvement in archaeology and the creation of early national policies concerning archaeological sites and monuments.

India's archaeological horizons expanded considerably in the twentieth century as research revealed the temporal depth and richness of its past. By mid-century, the focus turned increasingly to work on questions of prehistory and protohistory, which now consume far greater attention and resources than historical archaeology. The latter subfield, however, will play a larger role in twenty-first century Indian archaeology as the nation addresses such issues as heritage conservation, tourism development, and identity in a rapidly changing and diverse country.

Indian historical archaeology today faces many of the same challenges as other countries. The sites and monuments that are the primary archaeological objects of its research are often either part of crowded urban landscapes; highly visible and, consequently, vulnerable features of the rural countryside; or are still in active daily use. As elsewhere too, these sites are being destroyed at a rapid rate (Fig. 1). On the historical research side of the picture, India shares with other former European colonies the problem that many primary documents relevant to historical archaeology do not reside there, but are in Europe, principally in

India: Historical Archaeology, Fig. 1 The recent past is just as endangered as that which is thousands of years old. This unique early twentieth century roadside shrine, which has Mysore State constables for door guardians, is threatened by simple benign neglect and encroaching urban developments. (Photo by Barry Lewis)

British archives. The effects of these challenges are compounded by India's recent rapid economic growth, its significant urban and rural infrastructure problems, its complex central and state government bureaucracies, and its population density, which is growing at a rate that, if sustained, will result in India overtaking China as the world's most populous country by 2021.

Definition

In common with most European countries, India takes a broad view of the domain of historical archaeology. As practiced, it is best defined as the study of that part of the archaeological record for which there exists contemporary documentary evidence. Such evidence spans most of the last 3,000 years (Chakrabarti 2006: 287, 315), but the boundary between Indian history and prehistory is a fuzzy one.

Elsewhere, notably in parts of the Americas and Australia, the term "historical archaeology" is increasingly associated with the period of European colonial expansion, or roughly the past 500 years (Orser 1996: 23–8). While India has much to contribute to the latter research, this represents only one theme in a large and more complex research field (Fig. 2).

Historical Background

Late eighteenth and early nineteenth century antiquarians in India were committed to the Enlightenment belief in the interpretive value of reason as the primary means to understand the order of a knowable world. And there was plenty to know in India, for ruined cities, ancient monuments, art, undecipherable inscriptions, epic poems, and diverse literary traditions in a host of languages seemed to present themselves at every turn. Challenged by the evidence of India's past, these early scholars sought to construct an understanding of Indian history that mapped ancient texts and other documentary evidence onto the archaeological record (Chakrabarti 2010: 4–5, 9).

Questions about India's past attracted little government interest and support, except in such specialized areas as legal systems and land tenures. Antiquarian research was centered in a few scholarly organizations, the most famous of which was the Asiatic Society of Bengal, which formed in early 1784 under the leadership of William Jones. In South India, the less formally organized, but productive research of Indian and European philologists and antiquarians such as Colin Mackenzie and other members of the "Madras School of Orientalism," turned equally fertile ground (Trautmann 2009).

India: Historical Archaeology, Fig. 2 In rural India, the material remains of the past weave in and out of the present. This isolated tree and the carved stones placed against its trunk are a modern Naga shrine, which was created with *nagakal* (snake stones) recycled from an old shrine. (Photo by Barry Lewis)

Brilliant and committed though the antiquarians were, their work did not directly result in the creation of a distinct scholarly discipline of archaeology. They lacked a clear understanding of how old the "past" may be, practical methods that would enable them to reconstruct the past from archaeological evidence and relate it to the relevant documentary evidence, and essential concepts of time, space, and culture upon which to build basic interpretive frameworks for this past.

The creation of the Archaeological Survey of India (ASI) in the early 1860s marked the beginning of direct government involvement in archaeology, the first professional archaeologists, and the first steps toward a national policy concerning historical sites and monuments. Most research continued to emphasize historical questions, but archaeology's role was typically as a "handmaiden to history" (Trautmann and Sinopoli 2002: 499, 501), which often amounted to little more than illustrating history books with interesting photographs, drawings, and descriptive details.

The first half of the twentieth century was a high water mark for the ASI and for Indian archaeology generally. ASI announcement in 1924 of the discovery of the Indus civilization astounded the archaeological world and pushed back the dating of the emergence of urban society by several millennia. Although the nature and complexity of Indus society continues to be the object of considerable discussion, the discovery ensured that Indian archaeology had a seat at the table of international inquiry into the origins of civilization (Paddayya 2002: 143). It also pulled resources away from research on the historical periods and contributed in some respect to the growing sentiment of Indian nationalism and the push for independence.

Archaeology in the mid-twentieth century turned increasingly to research on protohistory and prehistory, sometimes to the near exclusion of questions of historical interest (Chakrabarti 2003: 1, 9). The focus shifted again in the late twentieth century when renewed interest in historical archaeology began to develop and expand its role as an active partner in the construction of historical perspectives (Trautmann and Sinopoli 2002: 517–8). This trend has opened a continuing dialogue as archaeologists, historians, politicians, and the public alike address fundamental questions such as who owns the past, the role of the past in modern identity politics, the public representation of the past in everything from heritage sites to school textbooks, and what should be national priorities and policies for the conservation of the archaeological record in a rapidly changing country.

Key Issues/Current Debates

India faces several challenges that have significant implications for historical archaeology, if not the entire discipline. These challenges include the impact of modern political agendas and religious fundamentalism on historical archaeology, the need for strong professional archaeological leadership, and the development of a sense of shared stewardship for India's past. Each challenge is considered briefly in turn, below.

Indo-Aryan Debate

Discovery of the Indus civilization had a strong impact on Indian national identity. The effects of this discovery were so great that, following Independence in 1947, when the most famous Indus sites became part of the new nation of Pakistan, Indian archaeologists launched major research efforts to discover comparable sites within the redefined boundaries of India (Chakrabarti 2003: 1; Rajeeve 2006). Fortunately, while it was an instance of archaeological research motivated mostly by national pride, it was also quite productive.

Recent examples of the sociopolitics of Indian archaeology have not been so simple or easy to work through. Current hot button issues include the language of the Indus script, the "Aryan Migration," the relationship between the Indus civilization and the Vedas, and the interpretive value of India's most ancient writings as historical texts.

Strictly speaking, the Indus civilization does not fall within the purview of historical

archaeology. Although authorities generally agree that it was a literate society, its script is undeciphered and may remain undecipherable given the few data at hand. Nevertheless, the many attempts made to read the Indus script have also fed a long-standing controversy about the origins of Indian civilization, whether it was a largely indigenous development or one that can be explained by the migrations of Indo-European speakers (the so-called Aryans) into the subcontinent (Trautmann 2005; Chakrabarti 2008). DNA evidence, which could potentially clarify the issue, has, thus far, proved to be equivocal.

The debate is further complicated by controversy that surrounds the possible relationship between the Indus civilization and ancient texts called the Vedas. Did the Indus civilization rise and fall before the Vedas, or was it the Vedic civilization (Trautmann 2005: xxxvi)? And, do the ancient texts possess interpretive value? Scholarly opinions of the value of the Vedas as historical texts range from positive to nil. Answers to these questions have implications for major issues in national politics, religion, and Indian identity (Chakrabarti 2008). They have even spilled over into heated controversies about how such topics are treated in school textbooks (Viswesvaran et al. 2009). These issues have no easy resolution, and historical archaeology is caught in the middle of the debate.

Archaeological Leadership and the ASI

The Archaeological Survey of India (ASI) celebrated its 150th year of operation throughout 2012. The ASI is India's key archaeological institution and one of the world's largest archaeological agencies. Founded in 1861, its government mandate and budget place the ASI at the center of Indian archaeology. Most states have archaeology departments, but their budgets, staff training, and priorities vary greatly within the limits set by state antiquities and monument legislation and appropriations. At least 25 universities also have archaeology programs, often as part of history departments. While some of these programs, such as that at Deccan College, enjoy international research reputations, others lack the support necessary to maintain active fieldwork (Chakrabarti 2006: 510–3).

ASI leadership, which should be of the highest quality, faltered over the past couple of decades (Lahiri et al. 2002). No single reason adequately explains the lapse. For more than 12 years, the ASI director general, who reports to the Ministry of Culture, was not an archaeologist, but a career civil servant deputed from the ranks of the Indian Administrative Service. Many ASI staff and line positions went unfilled. Few excavations and other research were published. The ASI handling of the Ayodhya controversy, the flashpoint of which was the destruction of a sixteenth century mosque by a mob in 1992, also left it open to criticism at several levels (Guha 2005; Chadha 2010: 230–1).

The ASI is working to reclaim its former leadership role. The current ASI director general is a qualified professional archaeologist, and recent changes in the upper echelon of the organization ensure that qualified candidates can now realistically aspire to the top ASI post. Moribund publications such as *Ancient India* and *Epigraphia India* have been relaunched, and the entire run of the journal *Indian archaeology – a review* has been placed online. The ASI website has become a useful and frequently updated information source, and the various ASI circles, or regional divisions, have implemented their own websites. ASI-administered financial assistance to state archaeology departments and universities was announced in late 2011 by the Ministry of Culture, which also proposed to create archaeological fellowships for young scholars.

Heritage and the Commitment to Stewardship

India needs a comprehensive, feasible national policy for the care of its cultural heritage, one that encourages the development of a widely shared sense of stewardship of the past (Fig. 3). Its rapidly growing population and the attendant sprawl of cities and towns, industrial development, and even changes in agricultural technology are destroying archaeological sites in every part of India. It is unquestionably true that the prosperity and well-being of today's India is of far greater

India: Historical Archaeology, Fig. 3 Political party slogans and other graffiti deface a late medieval fort gateway at Mudgal in northern Karnataka. Cultural heritage education in the schools may help to curtail such vandalism by instilling in students a conservation ethic and a sense of stewardship of the past. (Photo by Barry Lewis)

India: Historical Archaeology, Fig. 4 Remains of the tomb or *samadhi* of an early Chitradurga king rest largely forgotten in the middle of a cultivated field. Like hundreds of thousands of sites, it has yet to be documented in state or national databases. (Photo by Barry Lewis)

concern than the care of its ancient sites, but, while it is easy to concede this point, it is equally clear that the destruction of the nation's cultural heritage must be controlled as much as possible for the public good and for the understanding of India's past by future generations.

On the legislative side, the Indian government recently took several measures to support heritage conservation. Several new initiatives encourage active cooperation between the ASI, state archaeology departments, universities, and non-governmental organizations like the Indian National Trust for Art and Cultural Heritage (INTACH). Government also announced the creation of a National Mission on Monuments and Antiquities in 2007. Its mandate is to construct a cultural heritage database of sites, monuments, antiquities, and art treasures and actively promote a national awareness of India's cultural heritage (Fig. 4). In 2010, a major amendment to The Ancient Monuments and Archaeological Sites and Remains (Amendment and Validation) Act of 1958 created the National Monuments Authority, which adds teeth to existing legislation that protects

the immediate vicinity of national monuments and sites from unauthorized encroachments.

More than anything else, education will help to ensure that citizens become proactive stewards of the past for the sake of future generations. Promotion of a conservation ethic and pride in India's diverse cultural heritage in the classroom, a concerted effort by archaeologists to communicate what they do to local audiences and in local languages, prompt publication of research, encouraging the awareness of regional heritage priorities, and programs among local bodies such as village panchayats – all of these activities can make a difference.

International Perspectives

Archaeology was a European invention in India (Paddayya 2002: 119), and there is a long tradition of international collaboration, research funding, and training. In the best examples of international participation, such as the interdisciplinary project centered for more than 20 years around the ruins of the late medieval city of Vijayanagara (Fig. 5), the nation, its citizens, the historical and archaeological resources, and world archaeology derive considerable benefit from the relationship (Trautmann and Sinopoli 2002: 513–5). Regrettably, there are also counterexamples of international collaboration, which generate hard feelings in a country where the inequities of colonialism are still part of living memory (e.g., Chakrabarti 2003).

The future of international involvement in Indian archaeology clearly depends on the forging of long-standing research commitments in which Indian scholars are engaged in full collaborative partnership and where the international team brings skills, technology, or perspectives that are not readily available within India itself. While the *information* about India's past (about every country's past) may be said to belong to the world, Indian scholars must remain the primary creators of this information.

Future Directions

After decades in which prehistory and protohistory dominated Indian archaeology, historical archaeology is again emerging as an important research focus. However, its proper domain is now considered to be much broader than the fabled cities, palaces, and dynastic histories that interested the antiquarians of two centuries ago

India: Historical Archaeology, Fig. 5 Kota Shankara gateway at Vijayanagara, Bellary district, Karnataka. An ASI protected monument and UNESCO World Heritage site, the central core of Vijayanagara covers more than 25 km^2; archaeologists estimate that its fortified "metropolitan region" is roughly 600 km^2. Immense archaeological sites like Vijayanagara pose extraordinary heritage conservation challenges. (Photo by Barry Lewis)

India: Historical Archaeology, Fig. 6 A "hero stone" or *virakallu* that vandals uprooted and left abandoned among the ruins of a fourteenth century fort. It may eventually find its way into a local museum or collection or enter the pipeline that feeds the world market of stolen antiquities. (Photo by Barry Lewis)

(Settar and Korisettar 2002: xvi). The breadth of current research responds in part to the widely perceived need for perspectives of the past that speak equally to every Indian without prejudice, rancor, or disrespect. It is only then that researchers can expect the public to fully appreciate their cultural heritage, the value of archaeology, and why archaeology may deserve their support (Fig. 6).

Historical Evidence Is More than Texts

Indian history is based mostly on the authority of sources such as ancient texts, dynastic lists, inscriptions, coins, and the like (Chakrabarti 2010: 1–3). Historical archaeology's often-mentioned "handmaiden" role in the construction of history is due in no small part to its ready acceptance that this is the best part that archaeology can play (Ray & Sinopoli 2004). These constraints are largely self-imposed.

There are good reasons to cast widely for new types of sources that meet the criteria of valid and reliable primary evidence. For example, among nonliterary textual sources for precolonial and colonial India, historical archaeologists may find much of research value in relatively unexplored village-level records such as the *kaditas* or "black books" of the South (Hatti and Heimann 1991), *khanasumari* or house census records (Peabody 2001), and the archives of monasteries and *mathas*. Even the ocean floor is yielding valuable historical archaeological evidence as researchers investigate maritime and drowned terrestrial sites along India's thousands of kilometers of coastline (Gaur and Vora 2011).

Among other major sources that most researchers have yet to tap, historical cartography and high-resolution digital aerial imagery of India's landscape hold extraordinary promise for historical archaeology. As recent as the 1990s, it was hard to acquire aerial imagery in India, and inexpensive global positioning system (GPS) devices were no more accurate and precise than within tens of meters. Now, Google Earth and other spatial websites can show detailed images of most places on Earth at the expense of a few mouse clicks, and readily available GPS technology offers submeter accuracy. For those archaeologists who master the necessary technical geographic information systems (GIS) skills or whose research budgets can afford to pay for this expertise, a whole new world of historical archaeological spatial studies lies at their feet.

For their part, historians also have an important part to play in the creation of archaeological evidence. Harding's (1997–1999) exhaustive study of East India Company smallarms is a good example of historical research that has significant archaeological implications. By limiting his research to firearms, a category of material culture that played an important role in the establishment of British hegemony in India and elsewhere, Harding succeeds in placing it into social, political, and technological context in a way that earlier researchers could only imagine. Now, archaeologists and historians alike, when they walk the field

at Assaye or the fort walls at Srirangapatna, have a much more robust basis with which to evaluate the documented contribution made by infantry to these battles.

Historical Archaeology and the Rules of Evidence

Historical archaeology often gets little respect among historians, and even among some archaeologists, partly because its results sometime merely reaffirm that which we felt we already knew, and partly because these results often appear to be only weakly supported by convincing evidence that permits no other interpretation.

In historical archaeology, as in every research field, the power of an explanation, interpretation, or claim rests on the quality of the evidence that supports it. Many historians everywhere take a skeptical view of archaeological interpretations because they often appear to be based on little more than conjecture and personal bias (Henige 2005). This view can change only when it is standard practice for historical archaeologists to demonstrate unequivocally the validity and reliability of their research results. Each claim must meet the rules of evidence of both history and archaeology; such rules are not trivial, nor do they vary with the race, ethnicity, religion, gender, or political views of the researcher. If an interpretation fails to meet the rules of evidence, then it must be discarded. There is no middle ground.

These comments about the rules of evidence are particularly relevant to the situation of historical archaeology in India today (e.g., Guha 2005). Is archaeological evidence to be determined by political or religious ideologies or by the same standards and conventions that scholars demand of each other in the rest of the world? The answer will determine much of the future of Indian historical archaeology.

Indian Ocean: Maritime Archaeology

James W. Hunter III
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

The Indian Ocean is the Earth's third largest oceanic division and covers approximately 20% of its surface, with an estimated area of 28,350,000 mile^2 (73,427,795 km^2). It is bounded by three continents – Asia to the north, Africa to the west, and Australia to the east – and shares its southern

boundary with the Southern Ocean and Antarctica (Fig. 1). At its widest point, the Indian Ocean extends nearly 6,200 miles (9,977 km) between the southern tips of Australia and Africa. Small islands dot the Indian Ocean's continental rims, and several island nations, including Madagascar, Sri Lanka, and Mauritius, as well as the Maldives, Seychelles, Comoros, and Indonesian archipelagos, either border or are included within its waters. The Red Sea and Persian Gulf are both considered extensions of the Indian Ocean.

All of the world's earliest civilizations, including those in Mesopotamia, ancient Egypt, and the Indian subcontinent, developed around the Indian Ocean. Its waters are considerably calmer than those of both the Atlantic and Pacific Oceans, and characterized by powerful monsoons with prevailing winds that undergo predictable alternating seasonal shifts. As a consequence, the Indian Ocean hosted some of the world's first maritime trade networks, including those that developed between Mesopotamia and the Indus Valley c. 2500 BCE. Over the course of subsequent centuries, vessels embarked from ports in such diverse locales as Greece, Egypt, India, Persia, Indonesia, China, Portugal, the Netherlands, France, and Great Britain to engage in voyages of commerce, exploration, colonization, and warfare throughout its vast waters (Rais 1986: 13–36). Evidence of these and other cultures, and their interactions with one another and the larger Indian Ocean maritime landscape, are represented by a wide array of cultural heritage, including shipwrecks, submerged settlements, inundated landscapes, and abandoned infrastructure.

Definition

Keith Muckelroy (1978) originally defined the discipline of maritime archaeology as "the scientific study of the material remains of man and his

Indian Ocean: Maritime Archaeology, Fig. 1 Map of the Indian Ocean, showing its geographical boundaries (author)

activities on the sea." This has subsequently been expanded and refined to include "human interaction with the sea, lakes, and rivers through the archaeological study of material manifestations of maritime culture" (Delgado 1997: 259). Using these explanations as a benchmark, maritime archaeology in the Indian Ocean may be regarded as the efforts of individuals and organizations to conduct scientific investigation of the material remnants of the Indian Ocean's maritime past, including – but not limited to – evidence of trade, commerce, exchange, conflict, water transport technology, seafaring, coastal settlement, port and harbor infrastructure, and inundated landscapes.

Historical Background

At present, maritime archaeological studies have either occurred, or are ongoing, within Indian Ocean waters or coastal zones in the following places: Australia, Heard Island, India, Sri Lanka, Yemen, Egypt, Sudan, Eritrea, Kenya, Tanzania, the Seychelles, Mozambique, Madagascar, Mauritius, and South Africa. This number represents only 15 of the 44 nations and territories that share one or more coastlines with the Indian Ocean, and a very small overall percentage of the potential archaeological sites that are believed to exist within the oceanic division as a whole. Nonetheless, the discipline has clearly undergone significant expansion and development in the region over the past four decades, as evidenced by the research projects outlined below.

Australia and the Australian Antarctic Territory

Maritime archaeology in the Indian Ocean has its roots in the 1963 discovery of the shipwrecked United Dutch East India Company (VOC) vessels *Batavia* (1629) and *Vergulde Draeck* (1656) by recreational divers in waters of the Australian state of Western Australia. In the wake of extensive looting of cultural material from these sites, the finders of *Vergulde Draeck* transferred ownership of the wreck to the Western Australian Museum (WAM), which in turn pressed for protective legislation of all historic shipwrecks within the state's waters. Significantly, this action led to the development of a research-based maritime archaeology program at WAM, as well as federal legislation (the *Historic Shipwrecks Act* 1976) intended to protect historic shipwreck sites throughout Australia. Since the early 1970s, WAM researchers have conducted maritime archaeological investigations within coastal and offshore waters bordering Western Australia, and have assisted other Indian Ocean nations with the development and expansion of their own maritime archaeology programs and research (Staniforth 2011: 562–564, 576).

In the 1980s, a series of archaeological surveys were initiated at Heard Island, located within the sub-Antarctic region of the southwest Indian Ocean. Managed as part of the Australian Antarctic Territory, the island enjoys UNESCO World Heritage status and features a wide array of maritime heritage associated with sealing activities that occurred there between 1854 and 1877 (Fig. 2). Systematic investigation of these sites continued into the mid-2000s and included in situ documentation of artifact scatters, building foundations, tryworks, and a sealer's cemetery (Woehler 2004).

India

The emergence of maritime archaeology in India began with efforts to locate submerged elements of the ancient city of Dwarka in the late 1970s. Discovery of port infrastructure and several large stone anchors in the zone immediately offshore of the site's terrestrial components prompted a comprehensive investigation of these and other underwater features. It also served as a catalyst for the establishment of India's Marine Archaeology Centre (MAC) within the National Institute of Oceanography in 1981. In subsequent years, two other maritime archaeology centers were established at Tamil University and Andhra University, and an Underwater Archaeology Wing was created within India's national archaeology institute, the Archaeological Survey of India (Tripati et al. 2004).

Since the 1980s, maritime archaeological surveys and excavations have focused on several

Indian Ocean: Maritime Archaeology, Fig. 2 Trypots and tryworks associated with sealing activities at Heard Island between 1854 and 1877. (Image courtesy Eric J. Woehler, University of Tasmania)

locations dotting India's coast, including Poompuhar and Mahabalipuram. These sites include the remnants of ancient submerged ports established during India's early Christian era (seventh and eighth century CE). Features encountered at Poompuhar in both the intertidal and immediate offshore zones include remnants of brick structures, terracotta ring wells, and ceramics. Investigations at Mahabalipuram have revealed substantial submerged structural remains, including a portion of collapsed wall, dressed stone blocks, and an architectural assembly comprising steps and an associated platform (Sundaresh and Gaur 2011). These features may be associated with ornately carved stone temples reportedly observed near Mahabalipuram's shoreline by the first Europeans to travel to the region. Today, only one of the "Seven Pagodas" remains and was declared a UNESCO World Heritage Site in 1984. If their identity is confirmed, submerged elements of the site would be conferred the same status and degree of protection as their terrestrial counterparts, which would make Mahabalipuram the world's first – and currently only – World Heritage Site to specifically include underwater cultural heritage.

Historic shipwrecks have also been a focus of Indian maritime archaeology, and include efforts to identify and assess a number of wreck sites within the waters surrounding the historic port city of Goa (Tripati 2011). One of the more notable examples was discovered during a survey of Sunchi Reef, near the entrance to Goa Harbour. Archaeologists affiliated with MAC encountered the remains of a wooden-hulled vessel containing a variety of artifacts, including firearms, cannons, Chinese ceramics, and elephant tusks. Analysis of these items indicates the site represents an early seventeenth-century ship engaged in Indo-Portuguese trade and commerce (Fig. 3).

Sri Lanka

The 1963 discovery of an early eighteenth-century shipwreck at Great Basses Reef near Galle on the southwest coast of Sri Lanka was perhaps the first instance in which that nation's potential underwater cultural heritage was considered or even acknowledged; however, it was not until the early 1990s that the Sri Lankan government undertook an initiative to develop a program in maritime archaeology. With the advice and assistance of staff affiliated with WAM, a series of archaeological investigations have been carried out in Galle Harbour since 1992. These efforts resulted in the discovery, assessment, and identification of a wide range of maritime heritage sites,

Indian Ocean: Maritime Archaeology, Fig. 3 Fragments of Chinese porcelain recovered from the seventeenth-century shipwreck site at Sunchi Reef, India. (Image courtesy of Sila Tripati, Marine Archaeology Centre, National Institute of Oceanography)

including Indo-Arabian stone anchors, the seventeenth-century VOC shipwrecks *Avondster* and *Hercules*, and wrecks of a number of nineteenth-century iron steamships (Anderson et al. 2007).

In an effort to extend Sri Lanka's maritime cultural heritage management capacity, a national Maritime Archaeology Unit (MAU) was established in 2001. Its first major initiative was to excavate *Avondster*, as portions of the site were increasingly exposed and vulnerable to a variety of potentially destructive site formation processes. Between 2001 and 2004, MAU excavated sections of the vessel, surveyed and recorded its exposed remains, conserved collected artifacts, and prepared the latter items for display at the National Maritime Museum in Galle. The *Avondster* Project also served as a training program for MAU staff members, who received instruction in maritime archaeological methods and artifact conservation from experts affiliated with WAM, the Amsterdam Historical Museum, University of Amsterdam, James Cook University, and the Mexican Institute of Anthropology and History (Parthesius et al. 2005).

The Western Indian Ocean and Red Sea

In the Western Indian Ocean, the earliest systematic archaeological investigation of an underwater site is that of *Santo António de Tanná* (commonly referred to as the 'Mombasa Wreck'), a Portuguese frigate that sank while assisting in the defense of Fort Jesus, Mombasa Island (Kenya), in 1697. Recreational divers discovered the wreck in the 1960s, recovered a handful of artifacts, and brought them to the attention of the Fort Jesus Museum (FJM). An exploratory investigation of the site was organized by FJM in 1970, and artifacts recovered during this project confirmed its identity. In 1976, FJM requested assistance from the Institute of Nautical Archaeology (INA) at Texas A&M University to conduct a more comprehensive visual survey and assessment of the wreck. The results of this project, coupled with the significance of the material culture recovered during the 1970 investigation, motivated the National Museums of Kenya (NMK) to pursue further survey and excavation of the site. At NMK's urging, *Santo António de Tanná* was the subject of four seasons of field research organized by INA between 1977 and 1980. A conservation laboratory was established at FJM to treat over 6,000 finds recovered from the wreck site, and remains the only facility of its kind in East Africa (Piercy 2005; Lane 2012: 10–14).

In the same year *Santo António de Tanná* was identified, WAM maritime archaeologists conducted a survey of the remnants of an early European shipwreck at Boudeuse, a low-lying cay near Admiral Island in the Seychelles. Fishermen located the site in the early 1970s, and by the time

it was archaeologically surveyed, it had been subjected to extensive salvage that severely damaged its remaining hull structure and resulted in the recovery of at least 30 cannon and other artifacts, the majority of which have ended up in private collections. Despite these issues, enough evidence was collected to tentatively identify the wreck as *Santo António*, a Portuguese *nau* lost in 1589 (Lane 2012: 16).

For much of the 1980s, maritime archaeology in the Western Indian Ocean effectively ground to a halt; however, interest in the region and its underwater cultural heritage revived as a consequence of projects undertaken by organizations in Europe and the United States, as well as local institutions (Lane 2012: 31). In 1987, archaeologists affiliated with the French Department of Marine Archaeological Research located remnants of *Sussex*, a British East India Company vessel that sank near Bassas d'India in the Mozambique Channel in 1738. Subsequent investigations at the site resulted in the recovery of portions of the ship's Chinese porcelain cargo and other artifacts, while a survey of the surrounding reef led to the discovery of a cannon and two anchors that may be associated with *Santiago*, a Portuguese carrack lost at Bassas d'India in 1585 (Lane 2012: 19).

In 1990, scientists conducting a marine biology survey in Tanzania's Mafia Archipelago relocated an historic shipwreck that had been discovered by recreational divers near Juani Island in 1977. Among the many objects associated with the site were ten bronze cannons, three anchors, and a bronze bell bearing the inscription "H. . .&B H Co. 180_." Although now located within the boundaries of Mafia Marine Park, the shipwreck is yet to be comprehensively surveyed and identified (Lane 2012: 16).

Recreational divers were also responsible for the 1995 discovery of a shipwreck at Black Assarca Island off the coast of Eritrea. The mound of amphorae and scattered ceramics that comprise the site were investigated by INA in 1997, with support from the Eritrean Ministry of Marine Resources and the British Institute in Eastern Africa (BIEA). Based on comparison of the wreck site's ceramic assemblage with comparable pottery from terrestrial sites in Eritrea, Ethiopia, and Egypt, it has been tentatively dated to between the fifth and seventh centuries CE (Pedersen 2008; Lane 2012: 15).

INA archaeologists were also instrumental in the investigation of an Ottoman period shipwreck near Sadana Island, located along the Egyptian Red Sea coast. Excavations at the site between 1994 and 1998 resulted in the recovery of over 3,500 artifacts, one-third of which comprised Qing dynasty porcelain intended for the Middle Eastern market. The wreck's surviving hull remains are indicative of a large, three-decked vessel of Muslim ownership and likely Egyptian origin. In many respects, the Sadana Island site compares favorably to another shipwreck excavated near Sharm el-Sheikh in the early 1970s (Blue 2011: 504–505).

Between 1996 and 1999, a series of preliminary shipwreck surveys were initiated in the waters surrounding Ilha de Moçambique, a UNESCO World Heritage Site that was settled by Swahili peoples from the beginning of the first millennium CE until the late fourteenth century, after which it functioned as a shipbuilding center, trading port, and naval base for the Portuguese until the 1800s. Archaeologists affiliated with Eduardo Mondlane University organized and initiated the project with support from Brown University and the U.S. National Park Service. A number of historic shipwreck and other submerged sites were discovered as a consequence of these efforts (Lane 2012: 16–17).

In the early 2000s, maritime archaeology in Kenya was revived in a series of research projects undertaken by the University of Ulster's Centre for Maritime Archaeology (CMA) in collaboration with the NMK's Coastal Archaeology Unit, Tanzania's Department of Antiquities, the National Corporation of Antiquities and Museums of Sudan, University of Khartoum's Department of Archaeology, and the BIEA. The first of these involved systematic surveys of Mombasa Island and Harbor utilizing an integrated, interdisciplinary maritime landscape approach. Subsequent investigations included a marine geophysical survey of the Zanzibar Channel off Tanzania, and maritime landscape-based

investigations of the medieval town and port of Suakin on Sudan's Red Sea coast (Breen and Lane 2003; Lane 2012: 27–28).

Excavations at Myos Hormos and Berenice (Islamic *Queseir al-Qadim* and *Medinet-el Haras*, respectively) on the Egyptian Red Sea coast have provided valuable insight into harbors and their role in the facilitation and development of maritime commerce between Roman Egypt and trading centers in Arabia and India. Features encountered at Myos Hormos include part of a late first century BCE to early third-century CE Roman waterfront, jettisoned first-century CE amphorae near the entrance to the harbor, and a late first-century BCE or early first-century CE wharf or jetty comprised of numerous amphorae arranged in rows and buried beneath a packed earth surface. Functionally similar structures encountered at Berenice that comprise several large, linear coral blocks have been interpreted as seawalls or quays. These would have been used as moorings for vessels visiting the harbor and were constructed during the first and fifth centuries CE (Blue 2011: 499–500).

Recent archaeological investigations on Eritrea's Buri Peninsula have resulted in evidence for early human activity and adaptation in coastal environments. For example, at Abdur on the eastern side of the Gulf of Zula, Paleolithic handaxes and other stone artifacts dating to the Middle Stone Age were discovered in association with discarded marine mollusks and crustaceans – some of which appear to have been harvested and processed on site. Subsequent excavations at Asfet, Gelalo, and Misse East in 2005 and 2006 revealed early-middle Holocene occupations characterized by Later Stone Age artifacts discovered in association with marine shell. Taken as a whole, these studies provide evidence of early human exploitation of marine food resources, as well as some of the earliest coastal migrations of humans out of Africa (Beyin 2011; Blue 2011: 497).

Madagascar has hosted two maritime archaeology projects in recent years. The first, conducted in conjunction with terrestrial-based research that addressed the island's eighteenth-century Antandroy Kingdom, resulted in the discovery of four cannons and an anchor in shallow waters near Belitsaky on the southern coast. These objects are believed to represent *Degrave*, a British vessel that wrecked in 1703. In 1999, the wreck of a wooden vessel believed to be HMS *Serapis*, a British warship captured by American naval commander John Paul Jones during the American Revolution, was located at Île Sainte Marie. A team comprising American maritime archaeologists and researchers at the University of Madagascar conducted an excavation at the site in 2004 (Fig. 4); material culture recovered during these investigations was analyzed and conserved at the University of Antananarivo's Museum of Art and Civilization (Lane 2012: 20–21).

Between 2006 and 2008, researchers affiliated with the French not-for-profit organization Groupe de Recherche en Archéologie Navale located and investigated *L'Utile*, a ship owned by France's *Compagnies des Indes Orientales* that wrecked near Tromelin Island in 1761 while en route from Madagascar to Mauritius. The project was part of a broader UNESCO initiative to research the history of slavery in the Western Indian Ocean. Remnants of the wreck site comprised a widely scattered artifact assemblage, including iron cannons and anchors. In conjunction with the shipwreck survey, excavations were conducted on Tromelin Island in an effort to locate *L'Utile*'s survivors' camp (Marriner et al. 2010; Lane 2012: 20).

South Africa

Maritime archaeology has existed as a discipline in South Africa since the late 1980s; however, most research until very recently has focused on historic shipwrecks. While the vast majority of these studies have been restricted to the waters around Cape Town and along the nation's Atlantic (west) coast, a handful of wreck sites have been investigated in coastal areas that border the Indian Ocean. These include the British East India Company vessel *Arniston* (1815) and Royal Netherlands Navy ship *Amsterdam* (1817), lost on the south coast near Waenhuiskrans and at Algoa Bay, respectively. Remains of the Dutch warship *Bato* (1806) and British vessel *Brunswick* (1805) have

Indian Ocean: Maritime Archaeology, Fig. 4 A maritime archaeologist inspects a section of copper hull sheathing associated with the suspected HMS *Serapis* shipwreck site in Madagascar. (Image courtesy of Michael Tuttle, Serapis Project)

been located and investigated at False Bay, as has an as-yet unidentified nineteenth-century wreck site embedded in the beach at Plettenberg Bay (Werz 2011: 482).

Recent investigations at a handful of locations along South Africa's southern coast have expanded maritime archaeology's application and capacity to answer questions about the nation's earliest inhabitants. These sites comprise large shell middens associated with Middle to Late Stone Age occupations. Significantly, their material culture assemblages have provided evidence of shellfish extraction and use as an important subsistence and tool manufacturing strategy among pre-farming communities (Steele and Klein 2008; Lane 2012: 33).

Key Issues/Current Debates

Perhaps the most imminent issue currently confronting maritime archaeology in the Indian Ocean is the threat posed by commercial salvors to historic shipwreck sites within its waters. As noted previously, damage to the region's underwater cultural heritage at the hands of both recreational divers and treasure hunting concerns is by no means a recent phenomenon, and in many countries served as the catalyst for the creation of viable maritime archaeology projects and/or programs. In some locales, promotion of maritime archaeology and research-based initiatives has led to the complete, or near-complete, eradication of commercial activities.

Other nations, by contrast, have followed a very different path. One notable example is Mozambique, where a Portuguese salvage company has entered into an exclusive agreement with the nation's Ministry of Culture to conduct surveys and excavations of shipwreck sites around Ilha de Moçambique and along the adjacent mainland coast. Despite claiming to be a legitimate archaeological research organization, the company has insufficiently published results of its findings, limited access by other researchers to the sites it has investigated, and engaged in the sale of recovered artifacts (Lane 2012: 17–19). In addition, the scope of "research" it has carried out appears to be limited to European vessels that carried valuable commodities, and many of the sites it has salvaged have been abandoned without follow-up efforts at stabilization or preservation.

Another major issue facing maritime archaeology in the Indian Ocean has been the failure of all

but one nation in the region to accept or ratify the 2001 UNESCO *Convention on the Protection of the Underwater Cultural Heritage* (CPUCH). The lone exception, the Islamic Republic of Iran, has not yet conducted maritime archaeological research in the Persian Gulf, although a 2007 collaborative project between Iranian and British archaeologists to investigate submerged portions of the sixth-century CE Wall of Tammishe in the Caspian Sea holds promise for similar projects elsewhere in Iranian waters (Rekavandi et al. 2008). There is a clear need among Indian Ocean nations to revise their existing heritage legislation and/or adopt CPUCH. Doing so could enable each country in the region to create and/or develop its own maritime archaeology capacity, confront existing and emerging threats to its maritime heritage, and provide a framework for regional and international collaboration among relevant governmental agencies and research institutions.

Potential threats to the Indian Ocean's maritime heritage from significant seismic events and other natural phenomena, while infrequent, are nonetheless a very real concern and warrant brief mention here. In December 2004, an earthquake-generated tsunami that originated in Indonesia devastated coastal areas in several Indian Ocean nations. Among those affected was Sri Lanka's MAU, which lost its office and conservation facilities, equipment, archived site data, and numerous artifacts – including several conserved examples from *Avondster* that were being prepared for exhibition. Thankfully, no fatalities occurred among MAU staff and volunteers, and the unit's functional capacity was restored in a relatively short amount of time.

International Perspectives

As the birthplace of maritime archaeology in the Indian Ocean, Australia has assumed a leading role in promoting the discipline's development throughout the region. Australian maritime archaeologists conducted one of the first shipwreck investigations in East African waters, were instrumental in the establishment of Sri Lanka's MAU and Galle Harbour's maritime heritage survey, and provided assistance to the Sri Lankans in the wake of the 2004 tsunami. Heritage legislation created in Australia for the protection of historic shipwrecks and other maritime archaeological sites has in some cases provided a model for similar laws enacted in Indian Ocean nations. Similarly, Australian maritime archaeologists have advised their regional colleagues in the development and application of maritime heritage guidelines and statutes.

In 2009, the Maritime Archaeology Program at Flinders University in South Australia hosted an Australian Leadership Awards fellowship program that instructed practicing archaeologists from the Asia-Pacific region in underwater cultural heritage legislation and management and maritime archaeology field methods (Fig. 5). Included among the participants were individuals from three nations – Sri Lanka, Indonesia and Thailand – that share a border with the Indian Ocean. Australian maritime archaeologists were also instrumental in organizing the inaugural Asia-Pacific Regional Conference on Underwater Cultural Heritage. This meeting, held in Manila in 2011, counted maritime archaeologists from India, Sri Lanka, Tanzania, Kenya, Thailand, and Indonesia, among its attendees.

Future Directions

Australia, India, and Sri Lanka continue to develop their existing governmental and academic programs in maritime archaeology, and have embarked on efforts to conduct comprehensive surveys to inventory and assess maritime heritage under their purview. In the Western Indian Ocean and Red Sea regions, the Antiquities departments of Tanzania, Mozambique, and South Africa are being assisted by the Netherlands' Centre for International Heritage Activities to establish a regional Maritime and Underwater Cultural Heritage program and promote the development of maritime archaeology within these countries. Initiatives spearheaded by this collaborative effort include dive training, practical courses in maritime archaeological methods and legislation, and the development of designated underwater sites for heritage tourism. NMK

(Image courtesy of the Maritime Archaeology Program, Flinders University)

recently created a position for a "marine archaeologist" at the Fort Jesus Museum, maintains an inventory of historic shipwrecks in Kenyan waters, and is currently collaborating with the Chinese government and the School of Archaeology and Museology at Peking University to search for shipwrecks and terrestrial sites associated with the fifteenth-century voyages of Admiral Zeng He to East Africa (Lane 2012: 32).

Another collaborative venture that continues to gain traction is the work of CMA staff and students to apply maritime cultural landscape approaches to the inventory and investigation of maritime archaeological sites in Kenya, Tanzania, and Sudan. University of Ulster doctoral students have conducted maritime landscape studies in the Mafia Archipelago, and among several settlements along the Kenyan and Tanzanian coasts. In Eritrea, a joint effort organized by the University of Southampton and Eritrea's University of Asmara has utilized maritime landscape perspectives to investigate Adulis, a Red Sea port occupied by both the Romans and the Aksumite Kingdom during ancient times (Blue 2011: 503; Lane 2012: 28–31). Recently, the Institute for Arab and Islamic Studies at the University of Exeter has embarked on a 3-year, multidisciplinary, multi-period project that focuses on the maritime traditions of the peoples of the Red Sea and Arabian-Persian Gulf. The past 2 years have witnessed the commencement of underwater archaeological surveys in the waters surrounding the island of Réunion. This project, coordinated by the French *Institut National de Reserches Archéologiques Préventives*, is being carried out as part of a larger archaeological resources assessment of the island, and is among the latest in an increasing trend of maritime archaeology initiatives in and around the Indian Ocean.

[3]Repatriation Program, National Museum of Natural History, Smithsonian Institution, Washington, DC, USA

Introduction and Definition

Indigenous archaeological organizations can be divided into three categories: those explicitly dedicated to supporting community-based and

Indigenous archaeology, groups that are smaller sections of larger archaeology or anthropology professional societies, and organizations that have an explicit concern with Indigenous people in archaeology and historic preservation. Each supports Indigenous archaeology in different ways. What the organizations have in common is supporting the value that these communities bring to understanding the past and the engagement of Indigenous people with archaeology. There are several entries in this volume that provide background on Indigenous archaeology (please see the Cross-Reference section) as well as Atalay 2006 and Nicholas 2014.

Examples

Organizations Devoted to Indigenous Archaeology

Closet Chickens

A mentoring and support organization called the Closet Chickens was formed in 2001 to provide a place for discussion among Native American archaeologists. The group was formed after a conference at Dartmouth College, titled "On the Threshold: Native American Archaeologist Relations in the Twenty-First Century." At the conference, discussions centered on the ideas and perspectives participants had about being Native American archaeologists. Afterward, the conversation continued via e-mail and resulted in the decision to continue discussions as a more formal group. One of the group's major goals is to increase Native American participation in all levels of archaeology. The group includes members who are not Native Americans but support Native American inclusion in archaeology and approach archaeology from a collaborative perspective (Fig. 1). Outside of conferences, group members primarily communicate via an e-mail LISTSERV that was established when the group was formed in 2001. Members use the LISTSERV to share concerns and gain perspectives from others in the group, to share recent work and publications, and to organize conference sessions and publishing opportunities. As of August 2017, the e-mail list for the group has 56 members.

Sections of Larger Organizations Concerned with Indigenous Archaeology

Society for American Archaeology Committee on Native American Relations

The Committee on Native American Relations (CNAR) within the Society for American Archaeology (SAA) was formed in 1995 and is charged with bringing information to the SAA Board of Directors about issues of concern to Native Americans (Watkins 1995). The committee promotes understanding within Native communities about the value and relevance of archaeology, as it aims to foster better working relationships between Native American communities and archaeologists. The CNAR assists the SAA in being active rather than reactive to Native American issues, works with other SAA committees, and encourages Native American involvement in SAA to the greatest extent possible. The committee is composed of SAA members, and most often, a majority of the members are Native Americans. The committee emerged from a prior Task Force on Native American Relations when the SAA Executive Board felt that the work of the Task Force should continue.

Starting in 2008, the CNAR along with the Indigenous Populations Interest Group (described below) has hosted an annual reception for Native Americans, First Nations, and other Indigenous peoples who are participants or attendees at the Annual SAA Meetings. A central aspect of the reception is the acknowledgement of tribal peoples and the homelands where the meetings are being held. The reception ensures inclusion of these tribal communities at the annual meetings. It is notable that in 2008, the year of the first annual SAA Native American Reception, the SAAs were held in Vancouver on unceded Aboriginal territory. Due to the work of the CNAR and the Indigenous Populations Interest Group, the SAA meetings that year opened with a welcoming and witnessing ceremony with representatives from the Musqueam and Squamish First Nations whose land the meetings were held upon.

A second key aim of the reception is to provide networking for Native Americans and Indigenous archaeologists. Such networking has helped to build and nurture community-based research partnerships between Native American communities and Indigenous archaeologists.

Society for American Archaeology Native American Scholarships Committee

The SAA Native American Scholarships Fund (2017) is an endowment established in 1998 to foster a sense of shared purpose and positive interaction between archaeologists and Native Americans. Scholarships are open to all Native peoples from anywhere in the Americas, Alaska Natives, Native Hawaiians, and Indigenous Pacific Islanders and support archaeological training and study. The committee oversees the selection of awardees for four different competitive scholarships: SAA Arthur C. Parker Scholarship, several NSF Scholarships for Archaeological Training, SAA Native American Undergraduate Archaeology Scholarship, and the SAA Native American Graduate Archaeology Scholarship. Funding for the scholarships derives from book royalties donated by SAA members, a NSF grant awarded each year to the SAA, and a silent auction held during the annual meeting.

Society for American Archaeology Indigenous Populations Interest Group

The Indigenous Populations Interest Group (IPIG) within the Society for American Archaeology exists to promote the involvement of Indigenous communities in archaeologically driven research. As an interest group, membership is open to any interested member of the SAA, Native American, or non-Native American. The IPIG raises funds through a modest membership fee, and this money is applied toward the annual reception described above. At present the IPIG has around 200 members who meet at the annual SAA meeting to discuss topics of interest to group members. The IPIG is led by a volunteer member who organizes the annual meeting and the SAA Native American Reception.

Organizations Explicitly Supporting Indigenous Archaeology

The World Archaeological Congress (WAC) is a nongovernmental, not-for-profit organization and is the only representative worldwide body of practicing archaeologists (WAC 2011). The WAC's Code of Ethics (2017) commits to social justice for Indigenous communities, notes the obligation of its members to Indigenous peoples, describes how Indigenous cultural heritage belongs to Indigenous communities, acknowledges the special importance of human remains and sacred sites for Indigenous peoples, and recognizes the authority of Indigenous communities with regard to interpretation, study, exhibition, curation, and management of Indigenous cultural heritage. In addition to an Indigenous representative on the Executive Board, WAC has an Indigenous Council, composed of eight representatives from Indigenous communities worldwide. The WAC Code of Ethics begins with the understanding that WAC members are expected to view Indigenous peoples as the proper experts on Indigenous culture and are required to afford these people respect. Two WAC accords, the Vermillion Accord on Human Remains and the Tamaki Makau-Rau Accord on the Display of Human Remains and Sacred Objects, provide guidance for members on how to work with human remains and sacred material. A third WAC accord, Accord on the Protection of Cultural Property in the Event of Armed Conflict, forefronts the extreme physical and psychological trauma that comes from the purposeful destruction of cultural heritage during armed conflicts. The WAC membership is global and a large percentage of members identify as Indigenous. The 2005 WAC Inter-Congress in Auckland, New Zealand, was notable because the majority of the participants were Indigenous.

Other Organizations Supporting Indigenous Archaeology

A number of other organizations include a significant number of participants that support Indigenous archaeology but have other primary focuses. Two such organizations are the Association for Indigenous Anthropologists (AIA), found within the American Anthropological Association, and the National Association of Tribal Historic Preservation Officers (NATHPO).

Related Work

Intellectual Property Issues in Cultural Heritage

The Intellectual Property Issues in Cultural Heritage (IPinCH): Theory, Practice, Policy, and Ethics was a 7-year international research initiative based at Simon Fraser University, in British Columbia, Canada (IPinCH 2016). While not a formal organization in itself, the IPinCH project supported research into cultural issues of importance to Indigenous communities. IPinCH was a collaboration between community members, scholars, Indigenous organizations, policy makers, and heritage professionals. A number of symposia reports were produced on topics ranging from treaty relations to genetics and identity to the role of intangible knowledge in support of repatriation. The project was completed in 2017, but information about the projects, including the information produced by IPinCH, can be accessed at https://www.sfu.ca/ipinch/.

Indigenous Archaeologies

Desireé Reneé Martinez
Cogstone Resource Management, Baldwin Park, CA, USA

Introduction

With the recognition that archaeology has been used as a colonial and imperialistic tool, archaeologists worldwide have begun to redefine archaeological methods and theories to include multiple voices in the interpretation of the past (Preucel 1991). The last 30 years has seen an increase in the incorporation of Indigenous descendant communities as well as other marginalized populations in all stages of archaeological research. Indigenous Archaeology stems from this self-reflexive task and attempts to decolonize research agendas to acknowledge issues such as power, control, and authority in archaeological interpretation. Indigenous Archaeology practitioners state that Indigenous people *must* have a seat at the research table because their participation creates a more inclusive and nuanced depiction of the past (Nicholas and Andrews 1997; Smith 1999; Watkins 2001).

Definition

Indigenous Archaeology was first defined by George Nicholas in 1990 as "archaeology done with, for and by Indigenous people" (Nicholas and Andrews 1997: 3). Since that time a number of scholars have attempted to expand and identify its basic theoretical tenets and methods. Claire Smith and Martin Wobst (2005: 15) see Indigenous Archaeology "as an archaeology that is informed by indigenous values and agendas. Archaeological research is not *about* Indigenous peoples but is conducted *with* and *for* Indigenous peoples. Indigenous community members need to conduct and interpret the archaeological data for themselves but not at the exclusion of non-Indigenous researchers." Indigenous Archaeology "moves indigenous concerns to the center and orients archaeology to Indigenous systems of knowledge and power" (Smith and Wobst 2005: 15).

Wobst (2005: 29) further sees Indigenous Archaeology as a "decolonized archaeology that helps indigenous people obtain control over their material patrimony and where non-indigenous people can learn to use non-colonizing, non--statistic, non-capitalist ways of interacting with artifacts." An Indigenous Archaeology approach removes the lines between nature and culture and artifact and non-artifact in order to orient archaeology to an Indigenous perspective. Indigenous Archaeology embraces the study of the non-material, incorporating such subjects such as folklore, oral history, music, and dance. These nonmaterial subjects "may include stars and alignments, fauna and flora, geomorphology, and landscapes, colors, sounds and smells. We will have to allow for the 'natural' (that is 'non-artefactual') and 'cultural' (that is, 'artefactual') variables to be enculturated, to be significant to human action, and to articulate, like artifacts, with social life" (Wobst 2005: 28).

Nicholas (2008: 1660) defines Indigenous Archaeology as including eight principle characteristics: "(1) The proactive participation or consultation of Indigenous peoples in archaeology

(2) A political statement concerned with issues of Aboriginal self-government, sovereignty, land rights, identity, and heritage (3) A postcolonial enterprise designed to decolonize the discipline (4) A manifestation of Indigenous epistemologies (5) The basis for alternative models of cultural heritage management or stewardship (6) The product of choices and actions made by individual archaeologists (7) A means of empowerment and cultural revitalization or political resistance (8) An extension, evaluation, critique, of current archaeological theory."

Indigenous Archaeologies

In recent years, a number of scholars have begun to use the term "Indigenous Archaeolog*ies*" to signal that there is no single coherent theory or set of methods used within an Indigenous Archaeology approach. Instead, the term Indigenous Archaeologies reflects the "different experiences and approaches that have manifested themselves in a range of different practices" (Atalay 2008: 29). Each person and community interacts with the world around them differently, and these interactions are dynamic; they have changed, and continue to change, through time and space. "The plural form acknowledges the fact that different materialities exist around the globe and through time; and all these materialities are important building stones and points of reference toward theories of human materiality" (Wobst 2010: 18–9). Thus, the methods and tools used within an Indigenous Archaeologies paradigm will be influenced and controlled by an Indigenous perspective that is shaped by their experiences, history, and beliefs.

Historical Background

From archaeology's beginning as a discipline, Indigenous populations have been involved in its practice: as willing participants providing information on the location of archaeological sites, by practicing archaeology themselves (e.g., Arthur C. Parker), or through their objections to the wanton destruction of their community's traditional cultural places and items (e.g., Deloria 1969). As many minority and marginal communities worldwide attempted to fight for their basic human and civil rights in the 1960s and 1970s, Indigenous peoples questioned the relevancy of the archaeological research being mined from their communities. Some scholars have argued that academic studies have historically been used to support governmental policies that limited, removed, and suppressed Indigenous and other marginalized communities' rights and expressions of culture (Arnold and Hassman 1995; Fawcett and Kohl 1995; Lurie 1999: 108).

Spurred by postmodernism, feminist and Marxist thought, and changing political and social contexts worldwide, scholars started to review the production and reproduction of knowledge and power in archaeology. They questioned the obvious silence, or purposeful silencing, of Indigenous and other marginalized communities' perspectives in academic disciplines and governmental structures and policies (Deloria 1969; Smith and Warrior 1996). Scholars also started evaluating the impacts their research had on the communities under study and their own role as scholars in contributing to this silence. Indigenous Archaeology developed as a response to the academic appropriation of Indigenous pasts and to "address the need for decolonization. . .the lack of Native people in the ranks of professional archaeology (even though the discipline in North American thrives on the pasts of their ancestors), and Indigenous communities' desire to protect, manage, and even study their own heritage" (Silliman 2010: 218).

Postcolonial critiques further called for the decolonization of archaeological research and the creation of agendas that respond to Indigenous goals with Indigenous communities directing that research (Smith 1999: 142). L. Smith (1999: 142) lists 25 "projects" that Indigenous communities should be engaged in that supports the "reclaiming, reformulating, and reconstituting"

of Indigenous cultures and languages. The projects speak to themes such as "cultural survival, self-determination, healing, restoration, and social justice" (Smith 1999: 142).

Current Debates

Although a number of scholars are applying an Indigenous Archaeology approach to their work, others have questioned its usefulness. In his article "Aboriginalism and the Problems of Indigenous Archaeology," Robert McGhee argues that Indigenous Archaeology "assumes that Indigenous societies and cultures possess qualities that are fundamentally different from those of non-Aboriginal peoples" and that this "bears little resemblance to any reality" (McGhee 2008: 579). He sees an Indigenous Archaeology approach as a way to "appease Indigenous opposition" and that "such efforts are not only theoretically unsound, but are detrimental to both archaeology and to Indigenous communities" (McGhee 2008: 580). In particular, he argues that "proponents" of Indigenous Archaeology are essentializing Aboriginal communities by assuming that members of Indigenous populations have "unique qualities and abilities . . . and have a special relationship with and understanding of the natural world" (McGhee 2008: 583). McGhee also questions Indigenous Archaeology's sharing of authority and control over the use and interpretation of archaeological resources. He argues that by appeasing Indigenous community's claims to their "ethnically based rights," it strips archaeology of its "scientific attributes that make it a particularly powerful narrator of the past" (McGhee 2008: 591, 595).

Stephen Silliman (2010) and other Indigenous Archaeology practitioners who have shaped its development (e.g., Colwell-Chanthaphonh et al. 2010; Wilcox 2010) have criticized McGhee's position as a mischaracterization of the origins, objectives, and contributions of Indigenous Archaeology based on his limited review of a small number of academic writings on the subject. They argue that McGhee assumes that including Indigenous views (which he thinks are based in religious faith) into the practice of archaeology would exclude all other, and particularly scientific, perspectives. They collectively argue that if McGhee had delved further into the literature, he would find many successful and scientific examples of Indigenous Archaeology projects that contribute to the understanding of the Indigenous past without the exceptionalism that he fears. Indigenous Archaeology at its very core is community-based archaeology, one that "attempts to tell useful, respectful, and peopled histories that resonate with communities' senses of themselves, their pasts and futures, and their particular needs" (Silliman 2010: 218).

Colwell-Chanthaphonh et al. (2010: 232) reminds McGhee that Indigenous populations do have special rights to their participation within archaeological practice due to the numerous treaties, laws, and mandates that dictate such involvement. These rights are not ethnically based rights, "but long-established legal rights derived from the unique political status Indian tribes have in the United States formed over the centuries" (Colwell-Chanthaphonh et al. 2010: 232–233). Additionally, Colwell-Chanthaphonh et al. (2010: 233) contend that sharing authority with Indigenous communities does not change scientific attributes, but "merely asks people to recognize the impact that the practice of archaeology has had on descendant groups and the implications of perceiving Western science as the only 'real' way to explain things."

International Perspectives

The incorporation of Indigenous perspectives into archaeology is not solely limited to the discipline as it is practiced in the United States, Canada, and Australia. It is a worldwide movement as Indigenous peoples come forward to share their experiences interacting with archaeologists in their home countries and demand their voices be heard (see Smith and Wobst 2005; Bruchac et al. 2010 for numerous examples). Many are fighting for their basic human rights as they attempt to protect the bones of their ancestors and their cultural heritage.

Through its congresses and inter-congresses, the World Archaeological Congress (WAC) provides an international forum in which Indigenous and non-Indigenous people can exchange the results of their archaeological research; provide or obtain professional training and public education for disadvantaged nations, groups, and communities; help to empower and support themselves and members of Indigenous groups; and discuss strategies to conserve and protect archaeological sites. Since 1989, WAC has provided rich discussions about the ethics and treatment of the dead, the politics of the past, and the relationship among Indigenous people and archaeology (Smith and Wobst 2005: 5). Most importantly, WAC provides a network of well-attuned Indigenous scholars and like-minded individuals that Indigenous community members can turn to for professional advice, support, and encouragement.

Future Directions

The future of archaeology lies in the acceptance, incorporation, and integration of the multiplicity of voices to narrate the stories of the past. Archaeology cannot and should not support separate but equal research agendas with "scientific archaeology" running parallel to "Indigenous archaeology" or "feminist archaeology" (Martinez 2010: 219). Rather, archaeology needs to become a *communilog*: an area for discussion where all stakeholders participate and are self-critical to ensure that their research will not adversely affect the archaeological or descendant communities' rights (Martinez 2010: 219). There is room for everyone to participate in Indigenous archaeology. Indigenous Archaeology is just good archaeology (Martinez 2010: 219).

Changing Archaeological Pedagogy

In order to make Indigenous Archaeology mainstream, changes in current archaeological pedagogy are needed. Archaeologists need to "see themselves linked to the past that they are interpreting. Rather than seeing themselves removed from their research, they [should] see themselves as the end product of this historical process" (Benavides 2001: 2360). An archaeologist cannot speak ethically about a community's past if they do not engage its present and understand their role in it.

A number of archaeology field schools, initial training ground for future archaeologists, have begun to incorporate Indigenous perspectives into their syllabi by not only inviting Indigenous leaders and community members to discuss how archaeological projects impact their lives but also, and most importantly, having them as equal research partners who shape the research questions, participate in data collection, interpretation, and publishing (e.g., see Parrish et al. 2000; Silliman 2008; Martinez 2012). Exposure to working with Indigenous communities will allow students to understand the political and social context that they find themselves while practicing archaeology in their home country. They will also be exposed to the history and cultural setting of the Indigenous community whose material they will be working with.

Training Indigenous Archaeologists and Indigenous Community Members in Archaeology

Training Indigenous community members in archaeology to serve in the academy and/or to more actively participate in the cultural resources management process is essential to bringing an Indigenous Archaeology approach forefront. More indigenous archaeologists will help to create better working relationships between Indigenous communities and archaeologists by forcing archaeologists to confront and address Indigenous perspectives every day. While professors train Indigenous students in archaeology, Indigenous students in turn expose the professor to Indigenous issues and viewpoints. As Indigenous students move through the academy and become professors themselves, they will be able to train the next generation of archaeologists.

With government-mandated consultation for development projects becoming more common worldwide, Indigenous nations have become overwhelmed with the number of technical anthropological reports submitted to them for

review and comment. Although some Indigenous community members have had "on the job training" in archaeological methods and theories, many lacked the background to decipher the archaeological reports given to them. Indigenous community members trained in archaeological method and theory and the numerous national, state, and local cultural resource laws (with particular attention understanding the specialized jargon) are empowered to participate on an equal footing with academically trained archaeologists. It is imperative for Indigenous community members to be able to translate documents into their community's language (traditional or otherwise) so that the community can more effectively articulate potential project impacts to sites, places, and practices important to the Indigenous community.

None of these future paths can be obtained unless archaeology recognizes that Indigenous Archaeology should not be solely applied to and done by Indigenous populations, but by, with, and for *all* of the communities that they study.

Introduction and Definition

Indigenous archaeology comprises a broad set of ideas, methods, and strategies applied to the discovery and interpretation of the human past that are informed by the values, concerns, and goals of Indigenous peoples. It has been defined, in part, as "... an expression of archaeological theory and practice in which the discipline intersects with Indigenous values, knowledge, practices, ethics, and sensibilities, and through collaborative and community-originated or -directed projects, and related critical perspectives" (Nicholas 2008: 1660). This multifaceted approach to heritage has multiple goals in addressing a wide range of topics (Table 1) – from differences between Indigenous and Western epistemologies, to inequalities in representation, decision-making, and benefits flow, and to challenges relating to indigeneity and racialism – and assumes different forms and strategies in a variety of circumstances.

Indigenous archaeology has a dual, sometimes contradictory, nature since it may utilize the spectrum of methods employed in archaeology, ethnoarchaeology, ethnohistory, and related fields while also challenging them as an exclusive means to discover and interpret past lifeways. Although explicitly acknowledging the contentious, colonialist history of Indigenous peoples' relations in so-called settler states, a history that resulted in the loss of land, rights, and sovereignty for many groups, Indigenous archaeology lacks a single pan-Indigenous perspective or a cohesive set of goals, practices, and ideals. This can viewed as a strength, as well as the reason the term is sometimes pluralized. However, one commonality is that Indigenous archaeologists seek to mobilize knowledge about the past by ensuring that (a) archaeological practices are respectful of

Indigenous Archaeologies in Archaeological Theory, Table 1 Some topics of interest in Indigenous archaeology

local values, including treatment of ancestors (i.e., "human remains") and their belongings ("artifacts"), (b) local definitions of "significance" are employed in the identification and protection of heritage sites, and (c) the results of archaeological investigations are relevant to the living community, which is the primary beneficiary.

Indigenous archaeology does not necessarily reject the tenets of scientific inquiry, but does challenge the legacy of scientific colonialism and the hegemony of Western knowledge. Western knowledge tends toward a reductionist, hierarchical model of description and classification, coupled with a Cartesian sense of order and a search for universalist explanation; the focus is on things and other empirical measures. In contrast, Indigenous epistemology tends to be more particularistic and situational, composed of different bodies of knowledge (e.g., *Qaujimajatuqangit* ["Inuit traditional knowledge"]), and emphasized relationships between people and their relations, with each other, with ancestors and other-than-human beings, and with the land.

Indigenous archaeology both reflects and articulates with a variety of theoretical approaches in archaeology and heritage studies, ranging from the interpretative to the reflexive to the transformative. These include Marxist theory, cultural relativism, feminist theory, and postcolonial theory, as well as explicitly Indigenous constructs and practices. These various strategies are important in addressing the nature of "heritage," the degree to which it is integrated into people's lives, who benefits from it, and who controls access to it. Conceptions of law, sovereignty, property, identity, time, and wellbeing all converge to define heritage values and their tangible expressions.

Historical Background

The emergence of Indigenous archaeology in North America, Australia, and elsewhere by the 1980s was associated with a series of political events, cultural revitalization movements, and both lay and legislative efforts to reclaim land and religious freedom at the local and national levels. It does have a much longer developmental history. In the United States, for example, the American Indian Movement of the 1970s drew attention not only to the social and economic distress encountered by American Indian groups but also to the inequitable practice of archaeology in relation to American Indian cultural and human remains. National Repatriation Legislation of the 1990s (the National Museum of the American Indian Act of 1989 and the Native American Graves Protection and Repatriation Act of 1990) was derived largely from the American Indian Religious Freedom Act of 1978.

Coincident with these events was a series of developments in anthropology that included a shift toward a more subjective and critical orientation (e.g., Hymes 1974; Marcus and Fischer 1986) and increasing interest in applied anthropology. These trends were soon also apparent within archaeology and especially by the emergence of postprocessual archaeology in the 1980s (Hodder 1991). The particularistic, reflexive, and agency-directed orientation of this new approach marked a significant expansion of archaeological thought and practice, one that both extended and challenged the descriptive, normative approach of cultural history and the more science-orientated search for generalizations about human behavior and middle-range correlations between material culture and activity through processual archaeology. Postprocessual archaeology soon emerged as a suite of somewhat like-minded strategies – interpretive, critical, structural, Marxist, feminist, and Indigenous – that were relativistic and self-critical and recognized that archaeology was neither politically nor culturally neutral. Somewhat ironically, the development of this humanistic enterprise was aided by David Clarke's (1978) concerted attempts to make archaeology more analytical (and self-critical) and was furthered by his student Ian Hodder's efforts to use an ethnoarchaeological lens to relate material culture to ethnicity, among other goals.

The development of Indigenous archaeology must also be viewed in relation to Indigenous values, histories, worldviews, and ontologies (cf. Watkins 2000). There may be fundamentally different conceptions of heritage, for example, coupled with the absence of the familiar dichotomies that comprise Western worldview (Fig. 1). Thus, for Indigenous communities, the "real" and

Indigenous Archaeologies in Archaeological Theory, Fig. 1 Idealized Western worldview

"supernatural" may be part of the same dimension (Fig. 2), meaning that ancestral beings are part of *this* existence, not a different realm. This helps to explain why issues of reburial, repatriation, and the protection of the cultural landscape are so important to Indigenous peoples and has substantial implications for CRM/heritage management. Furthermore, individuals in many Indigenous communities believe that they do not need archaeology to tell them what they already know about the past through other means.

Thus, Indigenous archaeology represents the convergence of two different paradigms, one based in Indigenous epistemology and the other in the Cartesian empiricism of the West, as well as the intersection between identity, politics, religion, and science at the local, regional, and global scale.

Indigenous Archaeologies in Archaeological Theory, Fig. 2 Idealized Indigenous worldview

Key Issues

Theoretical Resonances

Characterizing the "theoretical nature" of Indigenous archaeology is not easy, given its multiple, sometimes contradictory, goals and applications (see McNiven 2016 for recent assessment). Nevertheless, there are a number of theoretical orientations and influences, clearly overlapping, that are significantly linked to or resonate strongly with Indigenous archaeology. These are Indigenous epistemologies and ontologies and interpretive, Marxist, critical, feminist, and postcolonial theory and practice (Nicholas and Hollowell 2007):

> Indigenous epistemology and ontology is concerned with ways of knowing based on local explanations and worldview. It is difficult

to generalize the wide range of Indigenous epistemological concepts, but many groups seem to share similar viewpoints that integrate the concepts of stewardship toward nature with one of shared use. Stories of creation often characterize humanity's relationship to the environment as an interactive one. That is, in creating the world, the animals established relationships with humans that gave humans responsibilities for maintaining a balanced world. Nature was often seen not as something to be 'conquered' or 'tamed,' but something to be aware and a part of. Humans were not outside of nature, but rather an active participant within it. In contrast to Western science, native science (see Cajete 1999) does not necessarily try to identify 'universal rules' for how things operate but rather focuses on situations of immediacy to particular groups of people. Observation over generations creates an intimate knowledge not only of plants and animals that exist but also the local ecological factors that influence the locations and actions of these communities, the local weather and seasonal patterns, and the interactions between those communities and the human ones. Each human group, therefore, is tied to its environment with its local ecology that does not necessarily govern its roles and responsibilities, but one which deeply influences the ways that the community integrates social, religious, and cosmological aspects of its culture with that of its environment. Populations utilize resources in such ways that contribute to the maintenance of those resources, and acknowledge the integration of nature and culture and of past, present, and future.

Interpretive archaeological theory, the cornerstone of postprocessualism, acknowledges that interpretation is a subjective exercise influenced by contemporary cultural values and historical contingency. It thus foregrounds reflexivity, dialogue, multivocality, and recognition of relative and situated nature of knowledge in seeking meaning in the archaeological record. For Native Americans 'there is a direct link between these calls for interpretations in archaeology and reburial issues, land claims, public archaeology, the presentation of the past, and so on' (Hodder 1991: 16). Phenomenological approaches, focusing on the experiential, are sympathetic to Indigenous perceptions, values, and actions relating to objects, places, and spaces, but may be viewed by some as yet another type of appropriation of local values.

Marxist theory provides a broad pallet of ideas of interest to archaeology. Those focusing on economics, cultural materialism, and cultural evolution generally are of little interest here. What is pertinent instead are Marxism's goals of knowing, critiquing, and changing the world by exposing power relations and inequalities, for example, and then identifying the means for social change through praxis— theoretically informed action (McGuire 2008). Marxism's interest in the dialectic, defined by oppositions or contradictions, both reveals and helps to explain the tensions encountered in the practice of archaeology. For example, we can view archaeologists as the bourgeoisie, monopolizing the means of knowledge production and being the primarily beneficiaries, and Indigenous peoples as the proletariat, still with limited means to, and benefits from, that knowledge production.

Critical archaeology, strongly aligned with Marxism, offers a cogent critique of the past (historical, archaeological) and of our knowledge of it and questions the political neutrality, norms, and class-based structure of science, history, and archaeology (e.g., Leone 1998). Like interpretive archaeology, it offers a critical analysis of historical ideological influences on the production of knowledge and the construction, presentation, and use of the past. Such analyses have emancipatory potential for marginalized and disenfranchised peoples by questioning both the circumstances in which their histories have been created (by others) and the assumptions made about their lifeways, actions, and motivations.

Feminist archaeology also challenges inequality and bias and evaluates knowledge claims relating to another marginalized group, women. Ambiguity and role of partial and/or situated knowledges are acknowledged, as is the fact that cultural systems are contingent and negotiated (Conkey and Gero 1997). Feminist archaeology promotes less hierarchical structure in fieldwork and the incorporation of multiple interpretations into the analysis. An early application of feminist practice in Indigenous contexts is Janet Spector's (1993) landmark study of a Wahpeton Dakota Village. Mainstream archaeology's reaction to Indigenous archaeology has been similar to its reaction to feminist archaeology. There are striking parallels between the two in terms of their developmental history, the critiques they offered, the body of new methods and theory that each developed, and their persistent marginal status within the discipline, rather than as approaches that are broadly transformative (Conkey 2005).

Finally, postcolonialism incorporates elements of the theoretical positions already noted, situating them explicitly in the context of colonialism and its consequences (see Lydon and Rizvi 2010 for examples). Indigenous archaeology is in fact very much a response to colonialism,

which is responsible for the application of the "indigenous" adjective that collected many distinct peoples into a single identity defined in contract to Europeans. Topics of interest to or incorporated by Indigenous archaeology include hybridity and continuity, identity, nationhood, resistance, and diaspora. Research relating to these and other topics has connected Indigenous peoples to other colonized peoples elsewhere in the world.

Indigenous archaeology resonates very strongly with these approaches, although connections can easily be found with other archaeological approaches, such as symbolic and structural archaeology (which some include within post-processualism). Structural approaches, for example, utilizing ethnohistoric and contemporary Indigenous sources relating to worldview, have been used in the interpretation of household space and settlement patterns in Canada (Oetelaar 2000). Martindale and Nicholas (2014) suggest bridging the universalist/particularistic divide using the notion of federated knowledge to connect multiple standpoints of interpreting and valuing heritage, archaeological or otherwise, while avoiding the usual asymmetry of power usually attributed to a Western vs. Indigenous knowledge comparison.

Not surprisingly, to date there have been generally very few explicit examples of Indigenous archaeology's connections with processual, evolutionary, or behavioral archaeology, all of which tend to operate at the scale of populations and which are seen to contribute little to the goals of Indigenous archaeology or to the needs of descendant communities. Indigenous archaeologists often utilize many of the basic tools of traditional (i.e., inductive, culture history oriented) archaeological inquiry in locating, describing, dating, evaluating, and interpreting heritage sites, but these may be customized to local conceptions of heritage or augmented by oral histories. While there has been a significant rise in tribal offices and Indigenous-led companies involved in heritage management projects that are producing "archaeological data," their alignment with Indigenous needs, values, and decision-making creates a hybrid approach to heritage management that includes more community involvement and benefits flow.

Realms of Application and Practice

There are four primary categories within which Indigenous archaeology – reactive, interpretive, reflexive, and transformative – in which theory intersects with practice. This overview is illustrative, not exhaustive.

Reactive

Many of the earlier manifestations of Indigenous archaeology were "reactive" against Western science and its applications through archaeology. Vine Deloria Jr. (1969) was the first to call attention to anthropology's often negative impact on American Indian groups in his landmark volume *Custer Died for Your Sins: An Indian Manifesto.* Shortly thereafter, archaeologists such as Thomas King, Eldon Johnson, and Roderick Sprague began calling attention to the issues American Indians were raising in reaction to the practice of archaeology; the suppression of Indigenous minorities included being distanced from their heritage. Many anthropologists and archaeologists provided supportive information for Indigenous land claims in the United States, Canada, and Australia in the twentieth century, but the Indigenous groups with a vested interest in the outcome, felt obliged to actively participate in the process, especially in relation to heritage preservation, education, community history and traditional knowledge, cultural revitalization, and repatriation of knowledge and objects of cultural patrimony.

In more academically focused questioning, Indigenous communities have demonstrated concern over the biases or limitations associated with traditional archaeological survey and site sampling methods, as well as with the adequacy of site significance evaluations and predictive models (especially when the latter are seen or believed to contradict community knowledge of traditional or precontact land-use practices) developed by archaeologists and presented as somehow more valid than those of the contemporary Indigenous populations. In addition, Indigenous groups have often questioned archaeology's claim to "stewardship" over the archaeological heritage, as well as the arbitrary divisions between "prehistoric" and "historic," and "archaeology" and

"history." Reactions to the limitations of traditional archaeology have also included extensive and concerted efforts by Indigenous groups to achieve greater participation in archaeological practice and decision-making in cultural resource management.

Interpretive

Indigenous archaeology projects frequently seek a congruence of oral histories, ethnohistorical sources, and archaeology, albeit not necessarily with equal levels of emphasis. This is illustrated in the contributions of Robert Hall, an Indigenous scholar whose collection of essays, *An Archaeology of the Soul: North American Indian Belief and Ritual* (1997), brought a new understanding of ancient ceremonialism informed by Native American beliefs and provided a foundation for more recent studies of Hopewell ritual. Oral histories have been especially important in defining heritage objects and places, including entire landscapes (e.g., as evident in the American Southwest and throughout Australia), but also connect Indigenous archaeology to the realm of landscape archaeology (David and Thomas 2008). Some scholars have challenged the use of oral histories in interpreting the archaeological record (e.g., Mason 2006) on the basis of subjective bias and other issues. Notably, validation of Indigenous knowledge by archaeological methods and data may not be important to local communities who are satisfied with their knowledge of the past through other means.

Political issues aside, Indigenous archaeology has in some cases forced archaeologists to reevaluate their interpretations of material culture or to consider alternative explanations informed by oral histories, folklore, traditional knowledge, and religious beliefs that may previously have been overlooked. Likewise, greater awareness has emerged as to the "tyranny" of Western values imposed upon ancient lifeways in the interpretation of archaeological remains. Indeed, alternative explanations of the past, informed by Indigenous sensibilities, can be construed as multiple working hypotheses that offer scholars ideas they might not otherwise have considered.

Reflexive

The emphasis on subjective perspectives and local values in Indigenous archaeology has, in some regards, helped to engage archaeological practice with descendant communities by emphasizing ethically and culturally appropriate behavior at all stages of research. This relates to a more extensive movement worldwide, championed by Maori scholar Linda Tuhiwai Smith, among others, to replace the methodologies of Western-based research with those more appropriate to Indigenous communities by asking the following: "Whose research is it? Whose interests does it serve? Who benefits?" (1999: 10). Increasing benefit sharing, community participation, and flexibility in the research process, along with recognition of the subjectivity of science, is a prominent feature of Indigenous archaeology.

Indigenous archaeology is necessarily reflexive in its nature as practitioners seek to identify the tools of Western science most conducive to their needs or personally evaluate what they're involved with in cross-cultural contexts. It is necessarily very collaborative, generally guided by strong community direction in setting project goals and identifying appropriate methodologies (e.g., Atalay 2012; Colwell-Chanthaphonh and Ferguson 2007; Watkins 2017). These often include standard archaeological survey, testing, and excavation methods that may be adjusted to local needs and coupled with ceremonial activities to honor ancestors and placate spiritual beings. Respect and trust are essential in the cross-cultural collaborations that are such a frequent element of Indigenous archaeology.

Transformative

Indigenous archaeology has been transformative in two substantive ways. The first is that it has provided Indigenous communities with a set of concepts and tools derived from Western science that can aid in identifying, protecting, and promoting aspects of their heritage in ways that are relevant to them. Here, the popular notion of archaeology for the sake of new knowledge from old things is eclipsed by an archaeology done for the sake of better people's lives and those of future generations (e.g., Atalay et al. 2014; McAnany

and Rowe 2016; Watkins 2017). This challenges the lasting legacy of scientific colonialism by ensuring that descendent communities are the primary beneficiaries of research conducted on their heritage. It is a project very much directed to the goal of decolonizing the academy by confronting long-standing imbalances regarding who makes decisions and who benefits, although often the rhetoric of "decolonization" has offered little practical means to achieve its goals.

The second transformation has been an appreciable broadening of the scope of archaeological theory and practice as a result of engagement – sometimes voluntary, sometimes forced – with the ideas, values, interests, and needs of Indigenous peoples. Coupled with ideas drawn from other approaches of postprocessual archaeology, many archaeologists have sought a more complete and critical understanding of the nature of archaeological knowledge and scientific objectivity that they want to activate through praxis (see McGuire 2008: 80). As a result, archaeology has gradually become more representative and responsible, with increased attention to ethics and issues of social justice, which is evident in the goals, structure, and code of ethics of the World Archaeological Association.

Current Debates and Future Directions

Indigenous archaeology is today part of the archaeological landscape but remains very much a project under development. It came into being during a time of social and political turmoil as economic and social minorities questioned the status quo of the governments and academies around them and soon after became engaged with discussions about the nature of archaeological knowledge and questioned Western conceptions of "the past." Always positioned at the margins of mainstream research, it has unfolded in such a variety of ways in different contexts that some contend it is rightly pluralized – "Indigenous archaeologies." As an element of post-processualism, but also in its own right, Indigenous archaeology has contributed to a broadening (and questioning) of archaeology theory and practice in ways that have been culturally enlightening and politically challenging.

Formed as it was during this time of social (and intellectual) unrest, it emerged in response to the Indigenous people's attempts to regain control over their own affairs and heritage as well as ideas emerging from within archaeology. It brings together Indigenous worldviews, political ideas, and socioeconomic thrusts for self-governance with a suite of archaeological ideas drawn from alternative approaches to archaeology. The result is an approach to archaeology that foregrounds multiple non-Western interests and values and respects (indeed requires) multivocality while integrating existing methodological ideas and interpretative universes. The questioning of basic principles and goals in archaeology, not limited to Indigenous contexts, has strengthened archaeology while also making it somewhat more relevant to descendant communities.

There have been a growing number of practitioners of Indigenous archaeology since its inception. While not all those who practice this are themselves Indigenous, the increase in the number of Indigenous persons attaining training in archaeology (experiential as well as academic) has led to a significant increase individuals who are trained to be able to integrate Western scientific methodologies with an understanding of Indigenous concepts about the natural world and humanity's place within it. These individuals are now aided by the immediacy of contact and knowledge exchange through the Internet and electronic Listservs (such as the ▶ Closet Chickens) that allow knowledge and experiences to be shared on a previously unknown global scale.

Indigenous archaeology has, and continues to face, a variety of challenges. Some critics have claimed it is a nonscientific exercise in political correctness or have leveled charges of exceptionalism and theoretical bankruptcy (McGhee 2009). Others have suggested that it eschews empiricism and embraces an extreme form of relativism. Some of these charges, especially relating to the lack of scientific goals or rigor, are reminiscent of early criticisms of feminism and post-processualism and harken back to the issues brought to the forefront by Trigger (1980) in his

call for recognition that archaeology has never been neutral or apolitical. Some explanations by Indigenous peoples of how things were in the past are, in fact, embedded in religious belief and thus do fall outside the realm of Western notions of science and history. What often has gone unacknowledged is that processual archaeology and postprocessualism may have more in common than recognized (Van Pool and Van Pool 1999) and simply operate at different scales. Furthermore, Indigenous archaeology may represent an extension of traditional archaeological methods conducted with, for, or by communities in CRM surveys, a pursuit of land claims, or supplementing or validating traditional histories.

Should Indigenous archaeology retain an identity separate from the mainstream, or should it be integrated? While this same question continues to be debated in feminist archaeology, it is complicated here by differences between Western and Indigenous values, worldviews, and so forth. Cree scholar Willie Ermine's (1995) consideration of the metaphysics of "inner space" allows for a more subjective insight into one's relationship with the scientific world. He offers the notion that an individual's experience through inward exploration, enhanced by working with elders and practitioners, can lead to a personal context within which to gain knowledge, as another way that Indigenous research paradigms can operate. His discussion of the space between these knowledge systems can provide a mechanism for Indigenous peoples who want to participate in archaeology but who feel uncomfortable or unwelcome in other settings. At the same time, Indigenous archaeology must have a presence in the broader discourse relating to both archaeological theory and practice.

The rise of Indigenous Studies programs in North America and other formerly colonized nations has also increased the reach of programs such as Indigenous archaeology. The availability of college-educated individuals provides not so much "experts" on Indigenous ideas and issues as much as individuals who possess the sorts of credentials recognized by administrators outside or the community. In this regard, the development of Indigenous Studies programs provides more nuanced perspectives that can influence a wider body of students than previously; individuals from Indigenous backgrounds who attend such programs are exposed to role models and ideas that expand upon Western concepts and integrate alternative means of understanding and talking about things.

Conclusions

Indigenous archaeology, as a recognized approach to interpreting, presenting, and discussing the human past, is growing stronger as more and more people become active in practicing the methodologies it proposes. However, as various subdisciplines and approaches to the study of the human past arise, practitioners must question the extent to which approaches might purposefully or inadvertently contribute to a weakening of the discipline through essentialism and Balkanization. To prejudge one perspective over another, regardless of the intent or purpose, creates an artificial hierarchy that threatens not only scientific exploration but also the development of alternative means of understanding how worldviews intersect or clash. Yet, with the growth of alternative means of knowing the lives and cultures of those who have gone before, Indigenous archaeology offers contemporary peoples alternative and more nuanced perspectives on the global past.

[2]Department of Archaeology, College of Humanities Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Indigenous archaeologies is a methodological approach that not only emphasizes collaboration with Indigenous peoples at every stage of research but also seeks to privilege Indigenous philosophies and knowledges in order to decolonize archaeological research and practice. Within the Australian context, the foundations of Indigenous archaeologies emerged in response to historical inequalities and continuing colonial nature of traditional archaeological research, which were at the forefront of debates within the discipline in the 1980s. The resulting emergence of "community-based archaeologies" in the 1990s coupled with the influence of postcolonial critiques of archaeological practice within international literature provided the basis for Indigenous archaeologies in Australian to establish its roots. Some of the critical issues that have been debated under the rhetoric of Indigenous archaeologies within Australia include repatriation of human remains and cultural objects; culturally appropriate archaeological methods from collecting institutions and practices; ethical standards and codes of ethics; intellectual and cultural property rights; cultural heritage management and legislative frameworks; as well as the impact of development and mining on cultural and archaeological sites of significance. Today, Indigenous archaeologies forms a large subfield of Australian archaeology where Aboriginal and Torres Strait Islander peoples' knowledge, interests, and concerns are considered crucial to the broader archaeological inquiry, despite the still-developing nature of the theoretical framework within an Australian context.

Definition

Indigenous archaeologies is not archaeological practice about Indigenous peoples, but rather practice that "is informed by Indigenous values and agendas" (Smith and Wobst 2005, 15). Indigenous archaeologies emphasizes a number of key objectives that seeks to challenge, reconceptualize, and transform traditional archaeological practices, including archaeological research that is initiated and controlled by Indigenous people while privileging Indigenous philosophies, interests, aspirations, agendas, and concerns (see Atalay 2007, 2008; Nicholas 2008, 2010; Nicholas and Andrews 1997; Smith and Wobst 2005; Watkins 2000). As a result, Indigenous archaeologies is considered to be a "change in mindset" (Smith and Wobst 2005, 7) toward Western forms of archaeological practices that can only emerge by undertaking collaborative or community-initiated research. In doing so, Indigenous archaeologies is considered a tool for engaging in the broader "decolonization project" in Indigenous research that has global significance for the recognition of Indigenous rights (Nicholas 2010).

Similar to gender, feminist, and queer archaeologies, Indigenous archaeologies is distinguished from other types of traditional archaeological practice both in terms of its ideological and methodological approach, which continues to broaden both theoretically and practically as Indigenous peoples progressively engage and thus transform

archaeological theory and methods. Nicholas (2008, 1660) presents the broad scope of Indigenous archaeologies in the following way:

> Indigenous archaeology is an expression of archaeological theory and practice in which the discipline intersects with Indigenous values, knowledge, practices, ethics, sensibilities, and through collaborative and community-originated or-directed projects related critical perspectives. Indigenous archaeology seeks to (1) make archaeology more representative of, responsible to and relevant for Indigenous communities; (2) redress real and perceived inequalities in the practice of archaeology; and, (3) inform and broaden the understanding and interpretation of the archaeological record through the incorporation of Aboriginal worldviews, histories, and science. In its broadest sense, Indigenous archaeology may be defined as any one or more of the following: (1) the active participation or consultation of Indigenous peoples in archaeology; (2) a political statement concerned with issues of Aboriginal self-government, sovereignty, land rights, identity, and heritage; (3) a post-colonial enterprise designed to decolonise the discipline; (4) a manifestation of Indigenous epistemologies; (5) the basis for alternative models of cultural heritage management or stewardship; (6) the product of choices and actions made by individual archaeologists; (7) a means of empowerment and cultural revitalisation or political resistance; and (8) an extension, evaluation, critique, or application of current archaeological theory.

Indigenous archaeologies is more than "just" an investigation of the past by archaeologists. It is a social, cultural, and political movement that can be a powerful tool for Indigenous peoples in redressing wrongs of the past, reclaiming cultural identity, reaffirmation, cultural revitalization, and maintaining heritage. As described by Piikani nation archaeologist Eldon Yellowhorn (2006, 137), internalist archaeology has reconceptualized archaeological practice from an Indigenous perspective which reclaims the archaeological record and connections to land through oral narratives in the local archaeological record.

In Australia, archaeological research done under the auspices of Indigenous archaeologies may seek to utilize creation knowledge, oral histories, lived experiences, and understandings to complement the knowledge derived from archaeological traces and interpretations of the past. Indigenous archaeologies in Australia will also draw upon non-Indigenous written texts from various disciplines including anthropology, history, linguistics, politics, sociology, and cultural studies to form a more comprehensive version about the past that privileges Indigenous philosophies, knowledges, and understandings.

Historical Background

While Indigenous peoples have never been passive bystanders to archaeology, archaeologists, and the closely related collecting activities of non-professional amateurs, the formative years of Australian professional archaeology are characterized by research that was mostly undertaken "on and about" rather than "with, for and by" (Nicholas and Andrews 1997, 3) Australian Aboriginal people; however, some exceptions exist. During her regional field surveys of the New England area of northeast New South Wales during the 1960s, pioneering Australian archaeologist Isabel McBryde sought out and interviewed local Aboriginal community members, "with the belief that a conversation over a cup a tea could yield as much historical insight as a week in the field" (Griffiths 2018, 44). McBryde would later go on to strongly advocate for Aboriginal people's involvement in site protection as a means to control their own heritage. McBryde, however, considers her proudest achievement is the number of Aboriginal students she helped who become archaeologists, including Robyn Bancroft, Mark Dugay-Grist, and Dave Johnson (Griffiths 2018, 49). In the early 1990s, while head of the Department of Archaeology at ANU, McBryde hosted the first major cohort (approximately 10) of Indigenous students undertaking archaeology (Kellie Pollard, 2010, personal communication). Many of these students completed their undergraduate degrees and constituted the largest group of Indigenous Australians to receive academic training as archaeologists.

During the 1960s when Australian professional archaeology was still in its infancy, Indigenous peoples were strongly advocating for basic human rights and were officially recognized in the Australian constitution during the 1967

Referendum (the 1967 Referendum meant that laws could be made [for the better or detriment] on behalf of Aboriginal and Torres Strait Islander people and that they could be counted in the census). Although this was a symbolic gesture, ideologies about the "extinction" of "traditional" Indigenous people were still prevalent. The following year Australian geomorphologist Jim Bowler discovered Mungo Lady's eroding burial at Lake Mungo in western New South Wales, which triggered further archaeological investigations in the area that continue today. In the mid-1970s, radiocarbon dates at Lake Mungo pushed the human occupation of Australian back to 36,000 BP, receiving international media coverage and garnering great public interest in Australia's Aboriginal heritage. With the changing political landscape within Australia during the 1960s and 1970s, including increased Aboriginal political movements to reassert and regain control over their heritage, culture, and identity, archaeological investigations at Lake Mungo became a focal point for debates around "who owns the past." In the decades that followed, the fate of Mungo Lady and Mungo Man's ancestral remains was also at the center of repatriation debates, culminating in their eventual return to the Paakantji, Mutthi Mutthi, and Ngyiampaa Aboriginal communities in 1992 and 2017.

In the early 1980s, the Australian archaeological profession experienced a watershed moment in the form of a speech entitled "Our Heritage, Your Playground" delivered by Tasmanian Aboriginal woman Rosaline Langford (1983) at the Australian Archaeological Association meeting in Hobart. In delivering this speech, Langford held archaeologists accountable for their past practices by arguing:

> The issue is control. You seek to say that as scientists you have a right to obtain and study information of our culture. You seek to say that because you are Australians you have a right to study and explore our heritage because it is a heritage to be shared by all Australians, white and black. From our point of view we say you have come as invaders, you have tried to destroy our culture, you have built your fortunes upon the lands and bodies of our people and now, having said sorry, want a share in picking out the bones of what you regard as a dead past. We say that it is our past, our culture and heritage, and forms part of our present life. As such it is ours to control and it is ours to share on our terms. That is the Central Issue in this debate. (Langford 1983, 2)

This speech and the growing sentiment surrounding it promoted further debates and discussion around "who owns the past," laying the groundwork for forging relationships between archaeologists and Indigenous peoples. As pointed out by anthropologist Gary Jackson and Australian archaeologist Claire Smith and (2005), significant changes emerged at this time contributing to the early stages of Indigenous archaeologies. These were identified as obtaining permission for fieldwork from Indigenous communities, involvement of Indigenous colleagues, access to sites and knowledge, control over publications, and dissemination of knowledge. Several key organizations and documents were also produced including the Australian Archaeological Association's (AAA) Code of Ethics in 1991, following the adoption of a similar code internationally by the World Archaeological Congress (WAC) in 1990, which began to shape archaeological research and "best practice." In response to the continuing colonial nature of archaeological practice, important postcolonial critiques of archaeological and related practices also emerged. In association with the emerging cultural heritage management (CHM) sector, the social, political, and theoretical movements of this period provided a platform for the development of "community-based archaeology" (see Greer et al. 2002). As Australian archaeologist Shelley Greer (2010, 48) points out, "the community-based response was to turn away from universalist archaeological concerns to documenting local Indigenous interests in heritage. Archaeology was put in the *service* of local Indigenous heritage, often engaging with anthropology in order to better understand and appreciate Indigenous practice." While community-based archaeologies provided the basis for Indigenous archaeologies to establish its roots, the influence of emerging international literature, particularly from the United States (see Nicholas and Andrews 1997; Watkins 2000), allowed Indigenous archaeologies within an

Australian context to flourish. Given the similarities that exist between Indigenous archaeologies and community-based archaeologies, these terms are often used interchangeably to refer to the same approach; however, Choctaw nation archaeologist Dorothy Lippert (2016) maintains Indigenous archaeologies is distinct from community-based archaeology due to its efforts to decolonize the discipline as well as work collaboratively with Indigenous communities.

Key Issues/Current Debates

While Indigenous archaeologies exist as a subfield within Australian archaeology, many would argue the principles of Indigenous archaeologies are today integrated as part of standard archaeological practice; however, the current debates that emerge from contemporary practice are still focused on primary issues including "who owns the past," demonstrating ongoing engagement with Indigenous peoples and the approaches of Indigenous archaeologies is still required to further decolonize the discipline. In other words, simply working collaboratively with Indigenous peoples does not necessarily result in archaeological practice that is decolonized; reflexivity is the key to ensure archaeological practice is ethically, politically, and socially engaged with Indigenous interests, aspirations, and agendas. As Gabrieliño (Tongva) nation archaeologist Desireé Reneé Martinez (2014, 3776) points out, "an archaeologist cannot speak ethically about a community's past if they do not engage its present and understand their role in it."

Consequently, Greek archaeologist Yannis Hamilakis (2007, 23–25) argues archaeologists have ceased to engage in the ethical or political implications of archaeology, with politically engaged archaeology now absent from the discipline. Recent critiques regarding the ethical and political nature of archaeology claim the adoption of ethical codes and best practice doctrines by the World Archaeological Congress (WAC), the Australian Archaeological Association (AAA), and other organizations have effectively "closed-off" or sanctioned the politics of archaeological practice from further consideration (Hamilakis 2007). Hamilakis (2007, 23) refers to ethical codes as a "decoy" used to avoid the political nature of archaeology. Furthermore, he interprets ethical codes:

> . . .as a tool, as a purely technical device, that can be used to achieve something else, most commonly to continue doing archaeology as normal, to declare that it is 'business as usual', now with the additional advantage of a clear ethical consciousness. (Hamilakis 2007, 24)

In many respects the same argument could be made in regard to the adoption of the collaborative approach of Indigenous archaeologies, which also allows archaeology to carry on "business as usual" under the assumption that archaeological practice is universally beneficial to those with whom one is collaborating (cf. Hamilakis 2007, 24). In-line with this argument, adopting a collaborative approach does not necessarily guarantee research is ethically, politically, and socially engaged with the concerns of collaborative partners.

Others argue a reflexive approach is essential to consider the ways in which positivist assumptions influence archaeological practice, in order to address the marginalization of Indigenous philosophies and interests (Giddings 2006, 200). A reflexive approach also allows for consideration of the asymmetrical power structures and unethical tendencies that are maintained by positivism, including the privileged position of a researcher to produce knowledges that may marginalize Indigenous philosophies and interests despite a collaborative approach (cf. Smith 1999, 176). Without such, positivism can remain the dominant paradigm through which the results of collaborative archaeological practice are interpreted. In doing so, the collaborative approach of Indigenous archaeologies is no more than "positivism dressed in drag," where positivism is simply given a "new guise" in order for research to proceed (Giddings 2006, 198, 200). That being said, researchers occupy a unique position in knowledge production with the capacity to engage with the ethical and political nature of their research, to undertake research that is ethically and politically responsible in order to

challenge this marginalization (Hemming et al. 2010, 101). According to Hemming et al. (2010, 96–97), research that seeks to challenge the marginalization of Indigenous rights, responsibilities, and interests is the basis for research that is ethically, politically, and socially engaged. The combination of collaborative and reflexive approaches is essential in order to undertake ethical and politically engaged research. Without a reflexive approach, we pat ourselves on the back for being progressive and fail to engage with ongoing ethical and political nature of our research. Therefore, collaborative and reflexive approaches go hand in hand to ensure an ethically, politically, and socially engaged archaeology is ethically, politically, and socially responsible archaeology.

In addition to this, the politics of representation and the relationships between archaeologists and Indigenous peoples have been explored (see Davidson et al. 1995). This relationship began as early as the 1930s with Indigenous peoples as "informants" and slowly progressed to involving Indigenous peoples throughout all aspects of the research process including the research design, consultation, ethics, fieldwork, and dissemination of information. It is this relationship and its development that continues to be a topical issue. Smith et al. (1994, 13) suggest that the traditional strength of Australian archaeology has been the analysis of sociopolitical issues including the relationships between archaeologists and Indigenous peoples and the change in power and control Indigenous communities have reclaimed over their cultural heritage. This type of Indigenous archaeologies which has also been termed "community-based archaeology" (Greer et al. 2002) began to shape much of the standard of archaeological research within Australia. During the 1980s and 1990s, debates related to ethics and the repatriation of "Old People's" remains placed pressure on disciplines such as anthropology and archaeology to become more culturally inclusive with research practices and ethics which included the deconstruction of past processual practices and decolonizing archaeology itself (see Smith 1999; Smith and Wobst 2005). Some of the key issues that continue to be debated include:

- The repatriation of human remains and cultural objects from collecting institutions
- The process of archaeological research, practices, and ethical standards
- Intellectual and cultural property rights
- Cultural heritage management and legislative frameworks
- The impact of mining, industrial waste and natural resource management, and housing development on cultural and archaeological sites of significance

International Perspectives

Internationally Indigenous archaeologies was first defined by American and Canadian archaeologists George Nicholas and Thomas D. Andrews (1997, 3) as archaeological practice undertaken "archaeology with, for and by Indigenous peoples." Indigenous archaeologies was later popularized by the publication of *Indigenous Archaeology: American Indian Values and Scientific Practice* (2000) by Choctaw nation archaeologist Joe Watkins. The World Archaeological Congress (WAC) has also played a significant role in the development of Indigenous archaeologies, with WAC conferences providing an international forum to discuss ideas and opportunities for Indigenous archaeologists (i.e., archaeologists who identify as Indigenous) to share their experiences. During the 2016 WAC conference in Kyoto, Japan, Choctaw nation archaeologist Dorothy Lippert expressed the importance of WAC in her personal and professional development due to these international networking opportunities (Lippert 2016).

As the pluralized nature of Indigenous archaeologies suggests, there are varying ways to undertake Indigenous archaeologies that reflect the dynamic experiences, knowledges, and cultures of Indigenous peoples globally this approach seeks to privilege (Atalay 2008, 30). Despite this, the experiences within Australia are similar to those internationally, and the approaches utilized in Indigenous archaeologies are often developed using models from Indigenous researchers, such as *Decolonizing Methodologies: Research*

and Indigenous Peoples by Maori academic Linda Tuhiwai Smith (1999), as well as Indigenous archaeologists themselves (i.e., Indigenous peoples who are formally trained in archaeology). Specifically, the Indigenous research agenda described by Maori academic Linda Tuhiwai Smith (1999, 116–117) has helped inform the way in which many Indigenous peoples are approaching archaeology in Australia. Smith's (1999) "Indigenous Research Agenda" privileges Indigenous epistemologies and acknowledges that Indigenous researchers also have a responsibility to ensure that research is conducted in culturally appropriate ways. Such an agenda ensures that elders or senior leaders are not simply entering into a process of "negotiation," but rather have complete control over the research process including proposals, development, methodology, interpretations, and the dissemination of information back to the community in a culturally appropriate and comprehensive manner. This approach considers complex issues relating to power imbalances and thus draws upon critical theory, postcolonial theory, standpoint theory, and a decolonization of research practice (Atalay 2007, 2008; Smith 1999; Smith and Wobst 2005; Watkins 2000). Therefore, it is an Indigenist framework developed for and by Indigenous peoples that is theoretically situated within post-processual and interpretative archaeologies – which ultimately reject a positivist view of science in search of new meanings and interpretations of the past. The issues that "Indigenous archaeologists" encounter in the research process are experiences discussed by many North American archaeologists (i.e., Nicholas 2010; Watkins 2000) and are critical for understanding relationships between the researcher and the "subject" in any research project involving Indigenous peoples.

Furthermore, Anishinaabe kwe nation archaeologist Sonya Atalay (2007) has discussed the use of Indigenous archaeologies for broader contexts. She highlighted the importance of "community-based participatory research" in Turkey, which involved archaeologists working closely with local people in understanding their cultural heritage. Atalay (2007, 253) argues that "Indigenous archaeology" is on the periphery of mainstream archaeological practices and is essentially a "practice that foregrounds knowledge and experiences of Indigenous peoples to inform and influence Western archaeologies as part of the decolonisation of the discipline." It is an approach that has global implications and can extend beyond Indigenous communities (i.e., local communities) – such as how it was applied by Atalay at Catalhoyuk, Turkey. It is evident through her research that some key components of this approach include identifying her privileged position, foregrounding local knowledge and experiences, the practicing of socially just research that has positive effects on contemporary communities, collaborative archaeology and the incorporation of worldviews, positive processes of decolonization, long-term goals and programs, working with communities to develop research questions based on community needs, using local knowledge about the best way to conduct research, and a flexible research plan and strategy. All these components are key to any research project regardless of ethnicity and therefore challenge the concept of "Indigenous archaeologies."

Future Directions

While Indigenous archaeologies as a methodological approach has progressed since it developed in the 1990s, some maintain Indigenous archaeologies is still developing. Choctaw nation archaeologist Dorothy Lippert (2016) argues Indigenous archaeologies "is not widespread. . . [and] we need to think about how Indigenous archaeology draws in and addresses colonial legacies and seeks to dismantle power structures that prevent Indigenous people from fully participating in sciences." In the article "Theoretical challenges of Indigenous archaeology: setting the agenda," Australian archaeologist Ian McNiven (2016) points out that Indigenous archaeologies has focused on collaborative aspects of archaeological practice and the move toward decolonization. As a result, the theoretical framework for Indigenous archaeologies is still yet to be defined and remain mostly

aspiration (also see Atalay 2008, 29). In addition to this, the contribution of Indigenous archaeologies to archaeological interpretation also remains underdeveloped, with Western archaeological knowledges maintaining an overall privileged position in the interpretation of archaeological materials. In order to address this lack of theorization as well as the privileged position archaeological knowledges maintain, McNiven (2016) argues addressing the dichotomies that lie at the heart of Western archaeological practice is key for producing understandings that privilege Indigenous philosophies and understandings.

Despite this, the exact constituents forming Indigenous Australian archaeologies are still in a process of discussion, debate, and transformation as more Indigenous peoples became actively involved in education, training, and research in archaeology and cultural heritage. With these arguments in mind, the full potential of Indigenous archaeologies in Australia has yet to be realized, partly due to the underrepresentation of Indigenous people within the discipline. For the most part, Indigenous archaeologies within an Australian context mostly refers to collaboration between non-Indigenous archaeologists and Indigenous community, rather than Indigenous archaeologists working for Indigenous communities (McNiven 2016, 28). This observation is supported by a decade-long survey undertaken by the Australian Archaeological Association (AAA), which reports the participation of Indigenous Australians in professional archaeology is low with Indigenous archaeologists (i.e., archaeologists who identify as Indigenous) comprising 2.3% of respondents in 2005 compared to 2.8% of respondents in 2015 (Mate and Ulm 2016, 171); however, this low percentage seems to reflect the low participation rates in the survey rather than being an accurate reflection of the archaeological profession, where it is estimated more than 20 archaeologists who identify as Indigenous are active in Australia (Mate and Ulm 2016, 172). Overall the survey concludes "the continued low participation rates of professionally qualified Indigenous archaeologists remain a challenge for the discipline" (Mate and Ulm 2016, 181).

In order to support and increase the number of Indigenous people participating in the archaeological profession, the Australian Archaeological Association (AAA) funds an Indigenous subsidy scheme for attendance to its annual conference, includes Indigenous Liaison Officer positions on its national executive committee, and is currently drafting a Reconciliation Action Plan (RAP); however, the AAA does not offer study scholarships equivalent to the Society for American Archaeology's (SAA) Native American Scholarships Fund, which was established in 1998 to support Indigenous peoples of America, Alaska, and Hawaii in their undergraduate and graduate archaeology education. In 2010 the Australian Indigenous Archaeologists' Association (AIAA) was established with the support from the Australian Archaeological Association (AAA) in hopes of promoting the active engagement of Indigenous people in archaeology and increasing the number working as professional archaeologists; however, the impact this organization has had on increasing participation rates of Indigenous people within the archaeological profession is hard to measure. Despite this, the AIAA has organized a number of sessions at the AAA's annual conference specifically to showcase archaeological practice and research undertaken by Indigenous peoples across Australia.

In recent years, a small number of Indigenous Australians have either embarked upon and completed PhDs in archaeology; however, comparing this to US situation where at least 20 Indigenous people have PhDs in archaeology (Lippert 2016), the small number of Indigenous peoples who have completed formal degrees in archaeology continues to be evident. Although the reasons for this have not been clearly identified and there have been no studies to address the issues to date, there are several reasons including the immediate employment of Indigenous graduates in government agencies and other organizations, the attractiveness of private consulting, and the commitment that Indigenous people already have in regard to caring for country as well as the fact that there may be few opportunities to leave current cultural and family obligations to undertake

full-time studies. What is evident is that Indigenous people engaging in the research, management, and protection of cultural heritage within their communities do not have the time or resources to leave the community to pursue academic scholarship – particularly the sustained study that is required for a doctoral thesis. Increasing participation and retention of Indigenous peoples in archaeology, cultural heritage management, and environmental sciences is therefore of critical importance. The representation of Indigenous archaeologists across all year levels (undergraduate through to research higher degree) must occur, as well as in all sectors that involve care, management, protection of Indigenous cultural heritage, as well as intellectual engagement through academic- and community-driven research projects. What is required is a stronger commitment to training cultural heritage "caretakers" through the implementation of archaeology and cultural heritage scholarships, cadetships, and research awards that plan for success across all degree programs from undergraduate to doctorate level.

In summary, Indigenous archaeologies within Australia have undergone significant change, transformation, since the initial development of Australian archaeology as a discipline in the 1950s; however, there is still a gross underrepresentation of Indigenous peoples participating in the discipline despite archaeology being professionally practiced in Australia for over 50 years. Although there is greater public awareness of the importance of Indigenous people, culture, and knowledge in Australia, mining exploration and urban development continue to impact on Indigenous cultural heritage and archaeological places of importance to our shared history. The complexities of these issues continue to be discussed and debated, and what becomes apparent is the continuous struggle for Indigenous recognition in a period of great political uncertainty for Indigenous communities who continue to feel the impact of colonialism. There will continue to be challenges for Indigenous archaeologies in Australia until issues of nationalism and representation of Indigenous peoples as a First Nation are negotiated. In short, it would seem that Australia is yet to realize the full potential of undertaking archaeology "with, for, and by" Indigenous peoples.

Introduction

"Indigenous archaeology" can be conceived of as a suite of responses to the legacy of colonialism in archaeology, while also reflecting a broadening and reconstitution of existing theory and practice designed to make the discipline more relevant and satisfying to descendant communities. It is an entity that is also defined by its engagement, often simultaneously, with issues relating to identity and ethnicity, the nature of knowledge, the flow of benefits derived from archaeological research, the indivisibility of tangible and intangible heritage, and different ways of knowing the world. Indigenous archaeology, depending upon who is involved and in what context, may be as much about the recovery of objects and information about past lifeways as it is about the sociopolitics of the endeavor and equally as much about community direction and involvement as it is about the decisions and choices of those individuals involved. It is thus very much a multifaceted and reflexive endeavor in which Indigenous epistemology(ies) intersect with archaeological practice in sometimes controversial, frequently challenging, but ultimately always enlightening ways (Fig. 1).

Definition

The term "Indigenous archaeology" and what it represents as an alternative means of examining the archaeological record are relatively recent developments, although there is some overlap with long-standing attempts toward archaeology's more open engagement with its various publics/constituents (e.g., "community," "vernacular"). The term is often pluralized to acknowledge its diverse applications in specific contexts, each shaped by the particular goals of the practitioners, by the methods employed, and by the distinct community values and historical circumstances that shape each project.

Indigenous Archaeologies: North American Perspective, Fig. 1 Davina Two Bears (Navajo Nation) is one of a growing number of Indigenous archaeologists now pursuing a career in archaeology (Photo courtesy of Davina Two Bears)

The earliest known use of the term referred simply to the Aboriginal (vs. European) component of a North American archaeological site (Dewhirst 1980), which is coincidentally the primary usage still in Australia. The term was not used with some consistency in its modern connotations until the late 1990s, with Nicholas and Andrews' (1997a: 3, note 5) reference to "archaeology with, for, and by Indigenous peoples." It was subsequently popularized by the publication of Joe Watkins' volume, *Indigenous Archaeology: American Indian Values and Scientific Practice* (2000), which critically explored late-twentieth-century relations between archaeologists and Native Americans, particularly in the context of reburial, repatriation, and cultural resource management. More recently, Nicholas (2008:1660) offered the first full definition: "Indigenous archaeology is an expression of archaeological theory and practice in which the discipline intersects with Indigenous values, knowledge, practices, ethics, and sensibilities, and through collaborative and community-originated or -directed projects, and related critical perspectives." Indigenous archaeology has now become a common-enough presence to warrant frequent mention in archaeology textbooks, despite the fact that some critics, Indigenous or otherwise, dismiss it as political posturing.

Indigenous archaeology is distinguished from other forms of archaeology that engage directly with descendant communities by its commitment to a particular, ethnically defined population. In this it is similar to feminist archaeology, which also has a comparably selective focus, but importantly both include practitioners who are not Indigenous or female, respectively. Of course, the notion of "indigeneity" is fundamental to Indigenous archaeology. The question of "who is Indigenous?" is always situational, necessarily framed in opposition to another entity, which historically has most often been a more dominant, colonizing society (Hillderdal et al. 2017). "Indigenous" thus generally refers to (formerly) disempowered, disenfranchised, or colonized peoples, although this is not the case in some parts of the world where indigenes may represent the state. Arguments that the people of Ireland, China, or India, for example, are "Indigenous" do have merit, but this falls outside of the realm of "Indigenous archaeology" as the term is employed here.

Historical Background

Indigenous archaeology generally refers to projects and initiatives associated with and especially those initiated by Aboriginal peoples in the United States, Canada, and Australia, but it also may include others (e.g., African Americans) who might be classified as "descendant communities." However, expressions of Indigenous archaeology also appear widely elsewhere, including in parts of Africa (e.g., South Africa, Kenya), New Zealand and the Pacific Islands, northern Europe, Siberia, and Central and South America (e.g., Nicholas 2010; Gnecco and Ayala 2011; Kato 2017). This has created discussion around "Who is 'Indigenous'?" and why some individuals do not consider themselves as such. In Central America, for example, only a small percentage of the native-born population currently self-identifies as "Indigenous," clearly reflecting important political and social issues regarding identity and self-representation.

The history of anthropology has been intertwined with the West's interest/fascination with the "Other," and foremost here were Indigenous peoples, especially in Africa, the Americas, and the Pacific. Many of the first "modern" anthropologists were also directly involved with archaeological pursuits, which led them to work closely with members of Aboriginal communities in the late nineteenth through early-to-mid-twentieth century. In North America, they included Franz Boas, Harlan Smith, Jesse Fewkes, Frank Cushing, Alanson Skinner, Arthur C. Parker (of Seneca descent), Julian Steward, and William Duncan Strong. Much of the impetus for these studies was aligned with the notion of procuring information before traditional lifeways were lost to "progress" and the ethnographic, archaeological, linguistic, and biological data obtained have proved to be of immense value to

anthropology but also often problematic to the relevant contemporary populations.

At the time, the community members who aided anthropologists and archaeologists did so primarily as paid or volunteer guides, laborers, and so forth. Most often unnamed, these individuals contributed substantially to the success of the projects and to the reputation of the directors. Only much later did the information gleaned from these studies come to have great value to those communities, sometimes a century or more later, to restore or augment traditional knowledge that no longer flowed from generation to generation. Nonetheless, Indigenous communities have generally benefitted little from these interactions. Furthermore, there was little, if any, opportunity to comment on, let alone influence, the type of research being conducted on their cultural heritage or involvement in decisions regarding the objects and information obtained. Indeed, throughout the twentieth century, increasing complaints were raised that anthropology and archaeology were continuing the colonial legacy of earlier times and that these disciplines were harmful and disturbing to many and were of little relevance or value to contemporary Indigenous populations.

By the 1960s, the increasing move toward cultural revitalization and politicization of Indigenous groups, coupled with a rapidly approaching postcolonial, postmodern world order and changing public attitudes in the wake of the Vietnam War and other events, contributed to the emergence of Indigenous archaeology in North America. Comparable situations emerged elsewhere, including the Outstation Movement in Australia and the independence of Zimbabwe (formerly Rhodesia) in Africa. Indigenous peoples not only demanded restoration of their lands and their rights but also more control over their own affairs, including those relating to archaeological sites and other aspects of their cultural heritage (Fig. 2).

During the latter part of the twentieth century, major changes took place in the relationship between Indigenous peoples and the dominant society. In the Americas, demands for tribal recognition, land rights, national sovereignty, and/or acceptance of ethnic identity and values were often as much inspired by cultural heritage issues as they were by calls for social justice and restitution. In the United States, for example, Vine Deloria Jr. clearly articulated aspects of Native American dissatisfaction, questioning the legitimacy and practice of anthropology and archaeology and the callous treatment of ancient human remains by scholars and museums. Following a decade of growing social and political dissatisfaction, the emergence of the American Indian Movement in the early 1970s brought national attention to many of the concerns of Native Americans, which ranged from issues of poverty, unemployment, and living conditions to what was seen as the desecration of ancestral remains and places of cultural significance by both archaeology and land developers. Increasing political clout and support from a sympathetic public resulted in the passage of federal legislation such as the

Indigenous Archaeologies: North American Perspective, Fig. 2 Robert Hall, of Stockbridge Mohican descent, here pictured during a Smithsonian Institution River Basin Survey in 1947, would later integrate Indigenous histories and religious knowledge into archaeological interpretation (Photo courtesy of Robert Hall)

American Indian Self-Determination and Education Assistance Act (1975) and the *American Indian Religious Freedom Act* (1978) in the United States. In other parts of the world, comparably significant federal legislation or court rulings on Indigenous rights were passed in New Zealand (*Treaty of Waitangi Act* [1975]), Australia (*Mabo v Queensland* [1992]), and Canada (*Delgamuukw v Regina* [1997]).

Relations between Indigenous Mexicans and archaeologists have followed a much different trajectory than in the United States and Canada. As Randall McGuire points out, Mexican archaeology has long been dominated by either a US imperialist agenda or a local nationalist that employed the concept of *indigenismo* to "glorify" mestizos (people of mixed Indian and European ancestry) as "the people of the nation" (2008: 152). As a result, there have been far fewer opportunities for Indigenous engagement with archaeology in northern Mexico and sometimes greater liability. Although this is changing, the situation is still well behind Maya involvement in archaeology in southern Mexico (McAnany and Rowe 2016).

Key Issues

In Boasian historical particularistic fashion, there can be no one history of the development of Indigenous archaeology. However, three themes have figured prominently in its emergence: (1) the treatment of ancestral remains (and sacred objects and places), (2) participation (or not) in archaeological/heritage management, and (3) cultural heritage and legislative concerns about the ownership of cultural and intellectual property. The examples provided for each are necessarily illustrative, not comprehensive.

Proper Care of Ancestors and Ancestral Remains

Perhaps the most contentious aspects of archaeology in the view of many Indigenous peoples have been the treatment of human remains and burial sites. From a scientific perspective, these are of immense scientific value, which led to the collection and study of skeletal remains by eighteenth- and nineteenth-century antiquarians and anatomists and later by archaeologists. Both ancient and recent skeletal remains were routinely sought and collected, including even the bodies of warriors who had died in battle with US military forces. These attitudes and practices were (and remain) a direct affront to their fundamental values, beliefs, and worldviews of living Native Americans.

In the 1970s, the American Indian Movement and various groups and individuals took direct action against archaeologists investigating human remains, but with little lasting effect. Reburial and repatriation issues subsequently rose to national and international prominence in the 1990s in response to the highly publicized looting of the Slack Farm site in Kentucky (1988) and similar events. The discipline examined its relationships with Indigenous populations in response to charges that it continued to exist within a structure of scientific colonialism and attitudes toward Aboriginal rights began to change from an institutional perspective. The adoption of the Vermillion Accord on Human Remains by the World Archaeological Congress in 1989, and the passage of the *National Museum of the American Indian Act* (1989) and the *Native American Graves Protection and Repatriation Act* [NAGPRA] (1990) in the United States directly addressed Indigenous concerns about the treatment of the dead, with scientific values no longer being the primary point of reference (Fig. 3).

For perhaps the majority of archaeologists, the reburial and repatriation "controversy" was largely unexpected and caused great consternation and confusion within the discipline. Some very vocally wondered if NAGPRA marked the end of archaeology at the expense of political correctness, while others seemed oblivious to it. In the years following the passage of NAGPRA, there was (and continues to be) widespread discussion about the goals and benefits of the scientific quest for knowledge relative to the need of descendant populations to have at least some control of their own heritage. This debate rose to international

Indigenous Archaeologies: North American Perspective, Fig. 3 The controversy involving Kennewick Man (the "Ancient One"), exemplifies different value systems between Western and Indigenous cultures (Composition by George Nicholas; base image courtesy of James Chatters)

prominence with the Kennewick Man (the "Ancient One") case (1995–2017), which was significant not so much for revealing differences in attitudes toward research involving human remains *between* scholars and descendant communities but especially so *within* each of those groups. Over the last decade, much of the rhetoric has softened as cooperative, and in some cases, collaborative projects with Indigenous communities have developed that involve ancestral sites and human remains (and which may include radiocarbon dating and aDNA analysis). No less important has been increased dialogue between archaeologists, between Indigenous peoples and archaeologists, and within Aboriginal communities as to the nature of archaeological research and the questions of what constitutes "heritage" and who benefits from research in this realm – an often-challenging discourse but one that always yields valuable (if often unexpected) outcomes.

CRM and Heritage-Related Developments

The care of ancestral sites has figured prominently in both the origins of and goals of Indigenous archaeology. By the mid-1960s, the preservation of archaeological sites was increasingly a focus of attention of CRM and heritage legislation in North America and elsewhere (e.g., *National Historic Preservation Act*, US (1966); *Australian Heritage Commission Act* (1975); and the *Canadian Environmental Assessment Act* (Reference Guide of Physical and Cultural Heritage Resources) [1996]). Such legislation was aimed at broad public values, but did not specifically address the concerns or desires of the Indigenous minority whose ancestors created the vast majority of archaeological sites in formerly colonized countries and who lacked the authority to make decisions about the preservation and management of their own heritage.

Some of the earliest instances of direct and meaningful involvement of tribal peoples in archaeology occurred in the United States. For example, Wendorf et al. (1956: II–IV) detail the manner by which the Navajo Nation may have given contract or salvage archaeology its start. From 1950 to 1953, El Paso Natural Gas paid for the archaeological work required for a gas transmission line from northwestern New Mexico across Arizona, directly employing five archaeologists and Navajo labor assistance as needed on salvage excavations. The program provided another benefit when the New Mexico District Engineer of the Bureau of Public Roads proposed and then supported the development of a similar archaeological program in connection with road construction in New Mexico, which led to the establishment of Highway Salvage Archeology in New Mexico on April 15, 1954 (Wendorf et al. 1956: VII).

Formal tribal involvement in archaeology in the United States subsequently began with the Zuni Archaeology Program (in 1975) and the Navajo Nation Historic Preservation Department (in 1978) as the first major initiatives to address specific concerns of Indigenous peoples relating to CRM and also to provide archaeological training. During the 1980s and 1990s, state government agencies and Indigenous organizations began to establish programs to train community members to monitor CRM projects. College- and university-level archaeology programs provided new opportunities for Indigenous people to gain access to important tools.

In recent years, changes in heritage legislation in North America now may require that archaeologists consult with Indigenous governments and organizations and to adhere to established protocols and permitting systems for field and research projects in their territory or for studying human remains. While well meaning, this consultation is sometimes severely hampered by the inability of Indigenous groups to respond to multiple requests to review reports, comment on actions, or even to answer information requests owing to limited human resources and other priorities confronting the community (e.g., inadequate housing, unemployment). For some, consultation does not go far enough, and what is considered desirable are more collaborative ventures in which the communities are equal partners in project development, operation, evaluation, and decision-making at the onset rather than as an afterthought (e.g., Dowdall and Parrish 2003). Others contend that Indigenous peoples should even take the lead in caring for their own heritage. In the United States, more than 175 tribes (as of October 2017) have taken on the responsibilities of the State government in managing impacts of federal projects on their heritage. In British Columbia, a significant number of First Nations have established their own heritage permitting systems (that the province acknowledges), along with many First Nations individuals now working as archaeologists.

Access to and Control over Tangible and Intangible Heritage

Throughout the early parts of the twentieth century, Indigenous peoples have been able to achieve greater and more meaningful control over tangible and intangible cultural heritage through various avenues, although there have been regular setbacks when legislation has been changed or legal precedents overturned. New or broadened legislation has ensured greater direct Aboriginal involvement, such as the requirement for First Nations in British Columbia, Canada, to review archaeological permit applications (*Heritage Conservation Act* 1996). In the United States, a 1992 amendment to the *National Historic Preservation Act* has allowed tribes to establish their own Tribal Historic Preservation Offices, enabling direct tribal involvement in heritage preservation on tribal lands.

A larger question involves who has access to, controls, and benefits from information derived from archaeological research and the control of traditional knowledge, especially for Indigenous peoples and other heritage-based communities who have historically had limited control over their heritage (Nicholas and Markey 2014). The appropriation, commodification, and unwelcome or inappropriate use of objects, images, and information relating to artifacts, sites, rock art, and other iconography is of great concern to Indigenous peoples, especially those who do not distinguish between tangible and intangible heritage or even between cultural and biophysical heritage. The costs to individuals, clans, and communities may be very high (e.g., loss of control over proper care of heritage, diminished respect for the sacred, the commercialization of cultural distinctiveness, improper/dangerous uses of special or sacred symbols by the uninitiated). In these examples, efforts to exercise control over tangible items define these conflicts less so than divergent views concerning the validity and appropriate applications of knowledge.

These issues are not restricted to modern times, but extend back well over a century in some cases, such as the case of ethnographer Frank Cushing who published information he obtained as an initiated member of the Zuni Priesthood of the Bow. Rights to intellectual property (from ownership of songs and images to control of traditional knowledge), as well as the recognition that tangible and intangible heritage may be one and the same, have long been integral elements of Indigenous societies. Such customary laws and values influence or direct Indigenous archaeological initiatives today. This may be evident in community specific and/or situational notions of appropriate care for/stewardship of heritage and indeed what constitutes "heritage." In the context of evaluating and protecting archaeological and heritage sites, Indigenous archaeology proponents may thus

seek criteria for "site significance" different from those of more traditional CRM policy and practice.

Current Debates

Some aspects of Indigenous archaeologies remain controversial, even in jurisdictions (such as the United States, Canada, and Australia) where real progress has been made in some sectors. The two decades-long debate over the fate of Kennewick Man indicated that issues related to the control by Indigenous groups (or by governments) of access by archaeologists to sites, objects, and human remains are still very much alive. A recent exchange in *American Antiquity* (see McGhee 2008, 2010; Colwell-Chanthaphonh et al. 2010, among others) explored many related concerns but focused on McGhee's arguments about two core issues: (1) Indigenous communities' power to control access and (2) the basis on which Indigenous peoples were accorded rights not held by other members of society. McGhee's concern was that such power could be used against science and, as a result, that society as a whole would be diminished because accounts different from those advanced by Indigenous communities would be suppressed. These are important issues with no easy answers: such control might be seen to be a continuation of the way the system has operated in the past, but merely with the population controlling the resources reversed.

A second issue, relating to this, concerns the recognition of specific descendant communities in the codes of ethics of the main archaeological organizations in North America. The first principle of the Society for American Archaeology's Code of Ethics (Stewardship) notes that "Stewards are both caretakers of and advocates for the archaeological record *for the benefit of all people*" (emphasis added) but fails to acknowledge any special connection that Native Americans have to that record. By contrast, the Canadian Archaeological Association fully acknowledges that distinction in its "Statement of Principles for Ethical Conduct Pertaining to Aboriginal Peoples," which identifies consultation, Aboriginal involvement, sacred sites and places, and communication and interpretation as necessary considerations for ethical practice. The recognition (or not) of the historical connections of descendant communities to the archaeological record, and the rights and responsibilities embedded in those connections, continues to be much debated in the context of Indigenous archaeology.

Another issue is the continuing effort to identify and address inequities that have long existed within the discipline, which have limited the ability of Indigenous peoples to have some control over their heritage and to benefit in the flow of research benefits. This follows the initial discourse on the sociopolitics of archaeology that first emerged in the 1980s in the context of critical and feminist archaeologies and that subsequently expanded with the concerns raised by Indigenous peoples and others regarding: (1) their absence or exclusion as participants in archaeology and (2) the persistent legacy of scientific colonialism in the discipline. Questions have subsequently been raised as to the role of archaeologists as gatekeepers of knowledge of the past, who not only controlled the flow of information but who generally were also its primary beneficiaries. It became evident that descendant communities were often shut out of decisions made as to their ancestral sites and received little social or economic benefits from research on their heritage. Despite the greater participation today of Native Americans, First Nations, Inuit, and Métis, it is very difficult to effect meaningful progress in these areas because most archaeologists are unwilling to share or relinquish decision-making, even when they support the increased participation of Indigenous peoples in archaeology.

Finally, there is the outstanding question of whether Indigenous archaeology should be distinct from "mainstream" archaeology or part of a more inclusive, less balkanized archaeology (Nicholas 2008). The development of Indigenous archaeology has followed a course quite similar to that of feminist archaeology, and although each

Indigenous Archaeologies: North American Perspective, Fig. 4 Common interests between traditional archaeology and Indigenous peoples may be less common than many realize

today is recognized as distinct entities, both remain on the margins of "mainstream" archaeology. While this has the advantage of offering a safe haven for those who promote strategies and perspectives influenced by Indigenous epistemologies and largely postprocessual methodologies (see the entry on Indigenous Archaeologies in Archaeological Theory in this encyclopedia), this positioning lessens the contributions of Indigenous archaeology to the discipline and ghettoizes it, so that its practitioners frequently tend to be "preaching to the converted." Indigenous archaeology will likely continue to have a dualistic presence, as would be illustrated in a Venn diagram that includes a partial overlap with the discipline (Fig. 4).

Future Directions

Indigenous archaeology grew out of efforts by marginalized peoples worldwide to challenge the imposition of archaeology on their lives and heritage. It has in a relatively short time developed into a distinct body of methods and theory(ies) designed to promote ethical and inclusive practices that will further broaden and democratize the discipline and stimulate new ideas that will significantly increase the scope of archaeology as a socially relevant, responsible, satisfying, and still scientifically sound discipline.

A growing number of archaeologists now make concerted efforts to include Indigenous perspectives within archaeological practice and interpretation. Initial volumes that tried to include Indigenous voices were generally collections of individual perspectives (Nicholas and Andrews 1997b; Swidler et al. 1997; Dongoske et al. 2000). More recent publications describe interactions between archaeologists and Indigenous groups (Ferguson and Colwell-Chanthaphonh 2006; Kerber 2006) and offer examples of active collaboration between archaeologists and underrepresented Indigenous populations indicative of the expanding approach to involving communities at the very heart of archaeological practice (Colwell-Chanthaphonh and Ferguson 2008; Silliman 2008).

International discussion on the situation among archaeologists and Indigenous communities (see the entry on ▶ "Indigenous Archaeologies: Australian Perspective" in this encyclopedia) is flourishing. Such edited volumes as Smith and Wobst (2005), Phillips and Allen (2010), and Bruchac et al. (2010) indicate that Indigenous archaeology is not a localized movement, but rather a global one. In Japan, Kato (2017) has initiated an Indigenous archaeological program to increase Ainu involvement and interaction with Japanese archaeology on the island of Hokkaido. There are also significant advances in both community-led and collaborative projects in Central and South America (e.g., Gnecco and Ayala 2011; McAnany and Rowe 2016), Africa (Schmidt and Pikirayi 2016), and elsewhere. This has been aided by the political and educational accomplishments of Indigenous governments, organizations, and communities in many parts of the world, often after countless years of struggle, as well as by developments within the fields of anthropology and archaeology, which are more responsive and inclusive than ever before. There are also today an increasing number of archaeologists who are Indigenous. Nicholas' (2010) edited volume of autobiographical accounts of 37 Indigenous archaeologists is but a sampling of a much larger and growing number. In their

Indigenous Archaeologies: North American Perspective, Fig. 5 The first all-First Nations CRM crew in Canada, directed by Nola Markey (O-Chi-Chak-Ko-Sipi First Nation). capacity as university professors, community heritage managers, or full or part-time CRM archaeologists, they are making substantial contributions by making archaeology more representative, by bridging different worldviews and legal regimes, and by serving as role models for others (Fig. 5).

The participation of Indigenous North Americans in the process of archaeology, and increasingly in setting its direction, has been a crucial step in helping archaeology move beyond the legacy of colonialism by ensuring the participation of descendant communities in meaningful and satisfying ways. As a result of what has now been achieved, we can no longer refer to "Indigenous peoples and archaeologists" without acknowledging that the latter category now includes a growing number of Indigenous archaeologists and archaeologists of Indigenous heritage in North America and elsewhere.

Indigenous Collaboration in Archaeology Education

Fabíola Andréa Silva
Museu de Arqueologia e Etnologia, Universidade de São Paulo, São Paulo, SP, Brazil

Introduction

During the last decades, several indigenous peoples and archeologists worldwide have committed themselves in the development of indigenous archaeologies. While engaging in reciprocal cooperation and exchange, they have triggered new investigation prerogatives in field research and in the interpretation and spreading of archaeological data and heritage management. Some indigenes have also acquired academic formation and became researchers of their own historical vicissitudes, assessing archaeological methods, techniques, and data storing and interpretation (Nicholas 2010). Indigenous oral history, cosmology, values, and knowledge have been incorporated within the construction of knowledge on the past. It may be said that, within their variegated manifestations, indigenous archaeologies are establishing themselves as critical and alternative approaches to traditional archaeological practices. Consequently, the parameters of archaeology education should be rethought and re-elaborated for the twenty-first century.

Definition

Indigenous archaeologies are carried out with, for, and by indigenous peoples. Research is not merely performed on them but aims at the production of knowledge with, for, and by indigenes. The following aspects must be taken into account: (1) the collaboration and dialogue with indigenous populations so that critical commitment and interactions could be achieved during the whole process involving the construction and broadcasting of archaeological knowledge, (2) the development of research issues and programs that would benefit indigenous population and would be approved by them, (3) the incorporation of indigenous perspectives in the investigation and interpretation of archaeological reports through the construction of mutual education between archaeologists and indigenous communities, (4) the respect toward local cultural rights for the management of cultural heritages, (5) the coupling of indigenous modes with the Western scientific type of approach, and (6) an assessment of how archaeological practice influences the populations' cultural dynamics (Atalay 2012; Kerber 2006; Colwell-Chanthaphonh and Ferguson 2008; Silliman 2008). As all pedagogical scholarships in archaeology in a wide sense, archaeological education will be strongly affected by these modes of archaeological practices.

Key Issues/Current Debates/Future Directions/Examples

As from the 1950s, archaeology has been transforming itself deeper and deeper, especially through postcolonial criticism, with an impact on the theoretical and methodological debate in the human sciences which triggered a gradual revision and redefinition of their practice from the perspectives of new ethical and scientific parameters. Among other items, multivocality and reflexivity as basic components of archaeological practices may be highlighted as from the elaboration of the project up to the publishing of research findings (Haber and Shepherd 2016; Habu et al. 2008). It is highly important to salient the defense of archaeological theories, methods, and practices that merge Western and non-Western knowledge and principles in the building of knowledge on past events and, at the same time, take into account differences and diversities of the points of view of the subjects involved in archaeological heritage management with more inclusive and democratic policies (Rubertone 2008). Archaeological practices would also consider the complex interrelationships (social, cultural, political, economical, and ideological) between agents and archaeological material at the local, regional, national, and world levels (Meskell 2009).

The "de-colonization of archeology" is experienced worldwide and within different research contexts as, for example, in Australia, New Zealand, United States, Latin America, and Africa (Colwell-Chanthaphonh and Ferguson 2008; Green and Green 2013; Haber and Shepherd 2016; Oland et al. 2012; Phillips and Allen 2010; Silimann 2008; Silva and Noelli 2015; Smith and Wobst 2005). New archaeological practices forward very different types of development and results. In fact, they reveal the possibility of several archaeologies and multicultural perspectives on the archaeological report. Contrastingly to archaeological research without interlocutors, in which archaeologists fail to build a dialogic relationship between them and the local community and in which bureaucratically established aims need not be changed, indigenous archaeologies redefine the several aspects of research, interpretation, and archeological heritage management and thus the parameters of archaeological education.

Within the present perspective in which several archaeological heritage appropriations are performed, archaeologists are the main agents of the archaeological record's valorization. Their expertise is of paramount importance in debates on the management of cultural heritage, the preservation of the environment, and the identification of historical and meaningful places. Their professional activities develop toward public policies, and frequently they are invested with the role of facilitators or mediators in the relationship between the different stakeholders involved in issues on cultural heritage (Fairclough et al. 2010; Liebmann and Rizvi 2008; Rubertone 2008).

The twenty-first century archaeologists should be prepared in theory and methodology to comply with their profession's new demands. The teaching and learning of archaeology should be adapted to these paradigmatic changes in archaeological practices. The future of archaeology during the twenty-first century will surely be defined by its commitment by the explanation of different cultural trajectories and processes within the context of identity and cultural heritages in the past and in the present.

Indigenous Intellectual Property Issues in Archaeology

Alvaro Higueras[1] and Julie Woods[2]
[1]Simon Fraser University, Burnaby, BC, Canada
[2]University of Massachusetts, Amherst, MA, USA

Introduction

Interests over heritage and intellectual property (hereafter IP) of indigenous peoples have arisen over the past 25 years in response to the increasing empowerment of indigenous societies. This empowerment has emanated, in different degrees and context, from the spread of democracy, the strengthening of the rule of law, the reinforcement of human rights, and more inclusive political scenarios around the world. The issue of IP has then interested both indigenous populations exercising their rights in such a context and legal researchers and social scientists, especially archaeologists, who monitor and interpret these developments (Anderson 2009, 2010; Atalay et al. 2014; Nicholas et al. 2010). On a broader perspective, sociologists have advanced the idea of the persistent imperial forms in Western democratic states which continue to affect, more than any other group, indigenous populations by imposing formal laws to the detriment of native laws (Tully 2000; Simpson 2008: 517).

Definition

The main issue in IP rights is claiming control and ownership of objects, values, and traditions which are at the core of indigenous societies' cultural heritage. Indigenous groups have initiated processes of reclaiming and restoring their traditions and ways of life. The initial movements were inward focused on cultural survival strategies and were followed by externally focused efforts to prevent loss of traditional knowledge (also known as folklore; hereafter TK), traditional cultural expressions (hereafter TCE), sacred sites, etc., using the tools of the dominant society and the international courts – property laws and conventions. Overall, these cultural survival movements were aimed at controlling the IP rights of the material and immaterial traditions at the heart of their society. Both stages are a result of community empowerment built on the often tense relationship between the observers (Western researchers and government enforcers) and the traditionally "observed" indigenous groups. Yet, despite these tensions and power imbalances, indigenous populations are experiencing increasingly favorable conditions as they move to secure rights to their IP through legal and non-legal means (Anderson 2005, 2009, 2010; Holcombe and Janke 2012; Janke 1999; Torsen and Anderson 2010).

Over the last several decades, processes of archaeological site protection and museum heritage repatriation (in the United States) and mutual understanding processes between indigenous groups and museums (in Canada) were pursued in earnest for the benefit of indigenous populations. At another level, new treaties (in Canada) were pursued to resolve the land rights of indigenous groups. The latter are essential: landscapes embody an important component in preserving and developing traditions. This is particularly difficult when indigenous communities have to confront with extractive industries eager to exploit their lands. At the most basic level, this process entails establishing a legal defense strategy for their creations and knowledge. At a higher level, it implies defending their ancestral lands (which are often under government control until the treaties are drawn).

Intellectual property is a central concept in today's Western society built on the idea that intellectual creations are the property of the creator (individuals or corporations). As such, IP laws entitle creators of assets such as songs and written works, either published or unpublished, to be copyrighted. In addition, other IP assets can be patented (technical inventions, in the realm of tangible assets) or trademarked (words, phrases, or logos that represent a brand) (Torsen and Anderson 2010).

Key Issues/Current Debates

What is the current IP status of TK in indigenous societies? Traditional knowledge is the broad and varied range of traditions and expressions that define the cultural makeup and dynamics of indigenous groups. This knowledge includes songs and rhythms, signs and icons, medicinal plant potions and food recipes, rituals, ceremonies and dances, oral poetry, stories and legends, and handicraft techniques created by ancestors and transmitted through generations. However, in most cases, this knowledge is not published and copyrighted (let alone patented as IP). Traditional knowledge includes then a broad range of cultural products that are witness to the long-timed and fruitful cultural endeavors of indigenous groups. Most indigenous groups consider themselves caretakers of community knowledge rather than owners of knowledge. Using the Western sense of property ownership, TK is considered to be "owned" by the group rather than by the individual. Yet this notion of group ownership has one practical issue quite alien to Western mores: TK is usually inalienable – not to be sold or given away by an individual group member. Thus, Western laws designed to protect knowledge are not well suited to protect TK and TCEs. Much of the TK and TCEs collected by western researchers and institutions were obtained without community consent.

In Western as well as in indigenous societies, intangible and tangible assets are tightly linked in the creative process. The ideal scenario is for creators to be able to control the reproduction, distribution, and consumption of their creative work and usufruct the gains or royalties from its sharing, rental, or sale. In this sense IP is defined here to include both types of assets: the ideas or concepts that result in material goods produced by the standards and procedures intrinsic to an intellectual asset. For example, the making of the hallucinogenic potion *Ayahuasca* requires a set of ritual, social, and technical skills devised and transmitted in secrecy by the shamans of Amazonian groups. On one hand, protections should exist to cover the rules and concepts that drive the production and consumption of the potion, and on the other hand, laws should exist to protect the potion itself. The complete process would fall into the realm of IP rights and would be proprietary to the group. This raises the question: Is *Ayahuasca* is as well protected as Coca-Cola? This is not the case.

In a debate involving IP rights, Michael Brown asked the important question: "Can Culture be Copyrighted?" (Brown 1998). Today Western cultural creations are widely copyrighted, trademarked, or considered trade secrets, with defined terms of limitation for certain creations (e.g., a literary work vs. the recipe for Coca-Cola). How should twenty-first-century societies with considerable advances in the issues of equal rights and ethnic self-determination (more so in the so-called First World countries) deal with indigenous societies that have a longer tradition in the use of their creations?

These are societies where knowledge is transmitted in an active legacy mode, within the community and without contracts or wills. Brown was skeptical about the IP proposals for indigenous groups (that is to say, IP rights in a Western mold) but eager to explore "basic mechanisms for the compensation of native peoples for commercial use of their scientific knowledge. . . and artistic creations" (Brown 1998: 204). Indeed, many of the legal disputes and grievances by indigenous groups are related, for example, to the patenting of medicinal and agricultural plants discovered, domesticated, or used for centuries. This said, Brown thought that a broad debate about securing ethical standards for cultural appropriation was not very propitious as it would set further apart indigenous circles from Western ones (Brown 1998: 195). Clearly, this is indeed what many wish to achieve while securing control of their IP. Brown is not sure about inherent, permanent right of cultural ownership and rather proposes to look into scenarios of joint stewardship. Is there a possible common ground to the needs of Western and indigenous societies to control their IP? Yes, but this ground diverges when "business" models might be considered to exploit IP. The international trend is slowly moving toward the more difficult stand: complete

control of the IP by their indigenous creators (Conway-Jones 2005). However, much reticence to this trend comes from institutions such as museums which seem to endlessly depend on their inalienable possession of artifacts (while opposing the inalienability of indigenous property).

The challenges indigenous groups face are related to legal issues in Western bureaucracy (Barrera-Hernández 2010). Why is it more difficult for indigenous groups to defend their intellectual rights? Why are their IP and their wish for self-determination (often leading to physical isolation) seldom accepted by Western society? Is their rebuff of the endless creativity cycle and drive to innovation proper to Western societies a problem? The indigenous realm will have, in most cases, the social backup and a tight network to pursue traditions flourished from decades of knowledge of their landscape, to recreate their vision of the world and their native identity and therefore own their traditional knowledge. What is it that they need to secure their IP and the survival of their cultural structures?

The Legal Background

Intellectual property law intersects with the discipline of archaeology across a full spectrum of activities: research, analysis, interpretation, curation, and repatriation. Archaeology will often rely on both tangible and intangible forms of indigenous knowledge. Throughout the world, indigenous knowledge, traditions, and sacred sites are at risk due to past and contemporary archaeological practices (see Oguamanam 2006; Yupsanis 2012). Current IP laws, international conventions, and academic traditions (by archaeologists) are primarily aimed at protecting artifacts, structures, and human remains. Indigenous IP has very limited protections.

The full recognition of IP rights in Western societies is backed by important legal instruments that guarantee to creators or inventors a degree of exclusive rights (with a set of time limits) and control to a wide range of tangible or material assets. These rights would also include assets such as music or recipes which in many cases – when ingredients, notes, and lyrics are not published – would be considered intangible or immaterial property. Although both Western and indigenous societies have creations in the intangible realm, it has been extremely difficult for the latter to attain the same level of control of intellectual creations.

Intellectual property law has its origins in the Statute of Anne of 1710 in Great Britain. This British copyright law was based on eighteenth-century European concepts of property, labor, and ownership centered on the individual. Early copyright laws were oblivious to indigenous cultural knowledge or traditional customary laws (Nicholas et al. 2010: 119; Torsen and Anderson 2010: 14). Since then IP laws have evolved based on distinct policies by nation-states with limited consideration and often ignoring indigenous concerns (Torsen and Anderson 2010: 20). While copyright laws are applicable and vary by nation, the Berne Convention establishes minimum standards of protection between states. More specifically, the 1995 Agreement on Trade-Related Aspects of Intellectual Property (TRIPS) provides multilateral protection for copyrights, trademarks, and patents (IP laws). Most countries are bound by TRIPS as members of the World Trade Organization (Torsen and Anderson 2010: 23). The 1996 World Intellectual Property Organization Copyright Treaty extends copyright protections further to compilations of data in digital form such as databases.

Intellectual property laws define the owner, author, user, and creator of works and expressions providing exclusive rights to the owner. Copyright laws provide protections for literary and artistic creations focusing on the form of expression rather than the content of the works. As such, indigenous knowledge and TCEs recorded in written, audio, or visual forms by archaeologists, often without informed consent, become the protected property of the archaeologist or the institution for which they work with no rights or benefits attributed to the traditional or indigenous community from which they were appropriated. Even when traditional knowledge is exchanged by

indigenous people to facilitate the repatriation of their ancestors and cultural materials, there is a risk of losing their rights to the TK if it is not clearly indicated that is confidential information that belongs to the community.

An additional concern with copyright law is that it does not prevent people from copying an idea, style, or method derived from an indigenous work. Copyright law only prohibits the copying of the actual work or TCE. Thus, TCEs in the form of stories, images, and material culture (tangible and intangible heritage) shared by archaeologists through public outreach, reports, and conferences can be misappropriated by nonindigenous people and transformed into consumer products, promotional materials, or other forms of expression without the consent of indigenous communities. TCEs are both cultural and economic resources for the community, and benefit from the use of TCEs should go to the community.

Copyright laws also make it very difficult for indigenous people to gain access to traditional knowledge and TCEs embedded in copyrighted materials. Most indigenous peoples do not own the collections stored in museums and other institutions. These collections often contain secret, sacred, or restricted information that may be subject to customary laws and practices (Torsen and Anderson 2010: 11). Without ownership rights, indigenous communities may be prevented from gaining access to audio, visual, written, and digitized representations of TCEs and TK that are important to the cultural survival of their communities. In some cases, access to copyrighted material is negotiated between owners and indigenous communities. This process is often time-consuming and expensive for indigenous communities as original property owners may now be deceased, difficult to reach, or may speak a foreign language (Torsen and Anderson 2010: 10).

Patent laws also pose problems for indigenous communities. Patents provide exclusive rights for a new product or process or a new technical solution to a problem. Traditional knowledge about biocultural materials and DNA/genetic information derived from indigenous peoples can be patented by corporations without benefit to indigenous peoples (Holcombe and Janke 2010).

United Nations Organizations Conventions

Despite the problems that IP laws pose to the tangible and intangible heritage of indigenous peoples, several UN conventions have been adopted that recognize indigenous values, knowledge, and rights to cultural survival.

The UN International Labor Organization (ILO) Convention of 1957 first recognized "indigenous and tribal" populations (usually minorities) as citizens of nations. Yet, this same ILO instrument promoted as well a destructive policy of integration and assimilation of these minorities into dominant societies. In contrast, the ILO Convention of 1989 promoted pluralism, self-sufficiency, group identity, and collective rights of indigenous peoples (Anaya 2004: 58–59). This convention also affirms that indigenous peoples are entitled to a harmonious relationship with natural resources following traditional patterns of use and land tenure (Anaya 2004: 144). Moreover, this last document encourages governments to work with indigenous peoples to protect their rights and their integrity and reject their discrimination. This UN declaration has been instrumental in the preservation of sacred sites in Australia and enabling indigenous people to gain access to sacred sites and burial grounds in Canada (Anaya 2004: 39–140).

The 2007 United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP or The Declaration) includes provisions expressed as rights: when put into effect by signatory countries, they extend protection for intangible cultural heritage. These provisions include indigenous peoples' rights to (1) "revitalize, use, develop, and transmit to future generations their histories, languages, oral traditional philosophies. . . and to designate and retain their own names for communities, places, and persons"; (2) "maintain, protect, and develop the past, present, and future manifestations of their cultures, such as archaeological and historical sites, artifacts, designs, ceremonies, technologies, and visual and performing arts and literature"; and (3) "maintain, control and develop their IP over such cultural heritage, traditional

knowledge, and traditional cultural expressions" (Nicholas et al. 2010: 123).

The 2007 UNDRIP and the 1989 ILO Convention both provide for the rights of indigenous people to be consulted and involved in activities that impact their heritage, traditional territories, lifestyles, and identities (Nicholas et al. 2010: 123). This is one of the most important instruments in the process of empowerment. However, it is a non-binding convention in UN member countries.

Finally, the Convention on Biological Diversity (CBD) provides protection for natural resources and genetic diversity which are critical to the continuity of indigenous cultural practices and the cultural survival of indigenous peoples. Although this convention is intended to promote global conservation efforts and genetic biodiversity, it may also have a direct impact on bioarchaeology research focused on the study of skeletal remains with the aim of understanding health and demographic issues. While not directly related to conventional issues of IP, the CBD may be a tool that indigenous groups can leverage to restrict the study of human remains and genetic material for ideological and ritual reasons in countries that are parties to the CBD.

Case Studies on Cultural Affiliation, IP, and TK

Indigenous populations challenge issues on IP in different spheres (see Mikkelsen 2012). Indigenous populations have sought ways to secure IP over their material and immaterial traditions, and they have also confronted situations that put that very same IP at risk. These issues are often the result of the historical circumstances of overtly imperialistic strategies in the last two centuries.

The conflict of indigenous groups claiming property to their IP occurs in different degrees around the world; that is, today indigenous groups confront different issues and have adopted different strategies to address their problems. Western powers dominated the world, starting and ending at different periods of time, with somewhat different imperial institutions. The different historical pathways and the distinct dominating strategies of the Spanish, British, and other empires have led to a diverse status for indigenous societies. This historical background is central to explaining the different challenges faced and acknowledged by indigenous populations. Indeed it will explain often their different attitudes toward their heritage and traditions: for example, some indigenous groups are worried about their material culture, while others are not. Archaeologists, who work, say, in British Columbia or in Bolivia, would witness these distinctions in the field: the challenges and demands by local groups in each region will be distinct. Indeed, their concern of IP over cultural material assets will differ: the issues of repatriation and research of indigenous sites, artifacts, and remains that are essential to North American groups are not a concern for a great majority of Andean South American groups. These issues are of more concern for minority groups in the Amazonian basin, who are attempting to stop the encroachment of their territories aimed at the extraction of goods and resources (Huertas Castillo 2004). Again, the attitudes toward their cultural heritage and concerns with ancestry will relate to historical issues, namely, the degree of integration into the mainstream society. In the case of Peru and Andean indigenous populations, they are today immersed in a market-oriented, Westernized, and neoliberal society, with some remnants of community-oriented tasks at the local level. Their level of *integration* with the current national society is an indicator of their concerns over heritage.

In the United States, archaeological site protection and resource protection laws were primarily focused on the rights of institutions rather than indigenous populations until the passage of the Native American Grave Protection and Repatriation Act (NAGPRA) in 1990. This Act was enacted to facilitate the repatriation of indigenous human remains, funerary objects, sacred objects, and objects of cultural patrimony from federally funded US museums. The Act had the important participation of indigenous people within the US borders, yet it contains ambiguous language and unfinished regulations that lead to sometimes contentious situations in the repatriation process.

The implementation of NAGPRA required two things, namely, (1) a thorough documentation of the artifacts in museums before the repatriation of the cultural assets to the descendant populations and (2) that federally recognized Tribes and native Hawaiian organizations must demonstrate cultural affiliation with their ancestors. This puts indigenous people in the difficult position of sharing TK and IP and the ritual and sacred meaning of artifacts with institutions and government agencies; it affects the very issue of IP control (Brown and Bruchac 2006). It implies that indigenous people must demonstrate kinship to the individuals or affiliation to the objects which were obtained decades or centuries earlier often under coercion to their ancestors. The proof of kinship is compared with the names and places recorded by the original collector many generations ago. There is an imbalance in this repatriation process, putting the burden of proof on indigenous groups to demonstrate ancestral links, cultural continuity and uninterrupted transmission, when, unfortunately, the social cohesion of these groups have been undermined by decades of neglect and social problems. In this scenario, museums, often with the participation of archaeologists, maintain possession and control of artifacts as well as the photographic, descriptive, and audio records (say, of traditional songs) in their collections.

By example, in February 1996, the mayor of Providence, Rhode Island, announced the sale of a carved wooden spear rest then in the possession of the city-run Museum of Natural History. From the museums' perspective, the utilitarian spear had been used on war canoes in the South Seas. However, from the perspective of *Hui Mãlama I Nã Kupuna O Hawai'i Nei* (group caring for the ancestors of Hawaii) and the Office of Hawaiian Affairs (OHA), the spear was an idol from the Sandwich Islands, the name given to the Hawaiian Islands in the 1770s by Captain James Cook. Both institutions wrote to the mayor of Providence disagreeing: "The fact that the ki'i lã'au was designed to hold, guard, and protect the spears of a kaua ali'i does not mean that it is utilitarian and therefore secular, having no religious significance. Such statements reveal a fundamental misunderstanding of the ki'i lã'au as well as the Western tendency to create differentiations where none exist" (Hui Mãlama 1996). So they claimed that the item is a *ki'i lã'au*, an object of cultural patrimony and a sacred object, which probably belonged to a warrior chief and possibly a ruling chief. Such an item would be an *'aumakua* image created by the *kaua ali'i* for the purpose of housing an ancestral spirit to care for his spears (Hui Mãlama 1996).

Hui Mãlama and the OHA urged a halt to the sale, claiming that the item fell under the protection of NAGPRA. Despite a brief period of consultation where culturally sensitive information was exchanged by the indigenous participants, the Museum formally rejected the NAGPRA claims. The dispute was vented in 1997 in the NAGPRA Review Committee meeting. Once again, the indigenous representatives shared culturally sensitive information about their ancestors, spiritual beliefs, as well as prayers and songs (National Park Service 1997a). The review committee agreed that the *ki'i lã'au* is a ceremonial object and recognized the reasonable kinship and cultural relationship between the OHA and *Hui Mãlama* and the native Hawaiians who created and used the carved wooden figure. Yet, the NAGPRA Review Committee took a narrow view of property law and determined that "there was insufficient information presented regarding the circumstances of the acquisition of the carved wooden figure to make an advisory finding concerning right of possession to the object as defined by NAGPRA" (National Park Service 1997b). The review committee recommended that the city of Providence reconsider its determination as the item is considered a sacred object under NAGPRA. Ultimately, the case was settled in 1998 with the Hawaiian organizations negotiating with the city of Providence to return the *ki'i lã'au* to Hawaii for permanent display.

This case raises many issues with the use of NAGPRA as a tool to repatriate culturally sensitive items. Fear of NAGPRA violations may convince reluctant museums to consult with federally recognized tribes and native Hawaiian organizations. Yet, implementation of NAGPRA is based on variable interpretation of cultural meaning and affiliation coupled with tight

interpretation of property laws by museums and the US federal government. In addition, the unequal exchange of information required to facilitate the repatriation process places TK and indigenous IP at risk. Many questions are left unresolved by this case: who gets to determine if an item is utilitarian or sacred? Can an item be both utilitarian and sacred, changing meaning based on its context of use? How can indigenous people demonstrate their cultural affiliation to their ancestors and culturally significant items without losing their IP rights?

In the case of sacred sites, natural resources, and landscapes, problems also arise when Western archaeological knowledge is used as a tool to restrict indigenous rights and contradict indigenous knowledge. By example, in a case from southeastern Australia, archaeological reports and interpretations of cultural landscapes were privileged over local indigenous knowledge in the construction of the Hindmarsh Island Bridge (Hemming and Treverrow 2005). The Ngarrindjeri nation is the traditional owner of this territory. In an effort to halt construction, Ngarrindjeri elders shared their TK about the cultural sensitivity of the area to be developed to protect the traditional Goolwa landscape. The authenticity of Ngarrindjeri knowledge was contested by local government council, which chose to rely on a natural resource management plan to avoid sites of significance. The council claimed that Ngarrindjeri people were no longer traditional and had devalued their knowledge of cultural landscapes and practices. The protests of the Ngarrindjeri people were ignored, and the development of the bridge resulted in the desecration of a Ngarrindjeri burial site.

In this case, the Ngarrindjeri leaders aimed to change the way nonindigenous people behave toward indigenous communities and traditional knowledge, namely, by privileging indigenous knowledge over Western archaeological. Rather than prosecute the council under the Aboriginal Heritage Act 1988 (SA), the Ngarrindjeri elders negotiated an agreement with the council that included an apology to the Ngarrindjeri people and changes to the way archaeology is practiced in the region.

An important case of the joint work between indigenous populations and "managers" is the grassroots resource preservation project in Kyrgyzstan (Pyburn 2009). The objective of the "Silk Roads" project, funded by IPinCH, has encouraged a public conversation about IP and cultural heritage in Kyrgyzstan. Indeed, its positive advances led to the inclusion of the Silk Roads sites on Kyrgyzstan's tentative list for UNESCO World Heritage status. This is an excellent case of a regional-scale project involving several sites. Again, the importance of the historical context: today's scenario of low awareness on heritage and traditions is the result of Soviet-era policies of creating a multiethnic nation with a Russian overarching tradition. In this case, Kyrgyz stakeholders from various backgrounds designed a series of small-scale, sustainable community-based projects aimed at the preservation and educational use of IP and cultural heritage. One of the projects along the road wished to improve the protection of a cultural heritage asset: an ancient temple with a strong local spiritual significance. The site was left unprotected after research and was in dire need of a plan to save it. The steps applied in the task were designed by the site director with the informed support of the people of Uzgen who debated and approved the measures. Arguments in the process included the cultural and spiritual importance of the site. Again, remember that these post-Soviet societies turned from an atheist society toward the rediscovery of traditional religions. The structure represents that long-appeased past.

Future Directions

The issues of controlling a group's IP also involve the management process that integrates indigenous populations and outsiders (mostly researchers). In many cases, the TK of indigenous communities is shared with archaeologists to aid in the protection of cultural landscapes and resources. The sharing or full protection of traditional knowledge is the prerogative indigenous societies have once they are in full control of their IP; it is not unlikely that parts of that

knowledge will be kept private as occurs with rituals and legends. The involvement of archaeologists is sometimes problematic, as they are made privy to this TK. Archaeologists can address this issue by choosing not to report or publish information related to TK or report on tangential outcomes after consulting with indigenous communities regarding what information is shared with the governments and the public. Another option is to coauthor reports with indigenous communities, enabling the communities to determine the appropriate level of disclosure of cultural information. In all cases, indigenous-centric archaeology protocols should be developed to supplement limited IP protections as nonlegal instruments to guide research and management, as has happened for the case of repatriation of indigenous artifacts in Canada. The examples have shown propitious room for arrangements away from the formalities and contradictions of the legal system.

Where are indigenous populations heading with their contentious but logical issues regarding the IP of their heritage? They are headed toward scenarios where they are able to legally contest, transmit, and uphold their concerns to the society at large. Increasingly, indigenous populations are gaining allies among archaeologists, heritage professionals, ecologists, economists, and global organizations who share a common interest in the protection and preservation of indigenous tangible and intangible heritage. While the motivation for joint research varies, this process has produced a more balanced approach based on a new gauging of indigenous and Western prisms in the study of indigenous societies. Yet, at the local and national level, indigenous populations continue to fight for cultural survival and sovereignty on a daily basis.

In many regions, there is still incomprehension among Western-trained archaeologists, heritage professionals, and governmental organizations, let alone society at large, as to why indigenous populations deserve the privileges of self-governance (in the best case scenario) and why they aim to block governmental decisions that would not only benefit them directly but also benefit society at large in financial terms. However, the crux is in the benefit to their IP and TK on the long term or, put plainly, the endurance of society and landscape. Rather, any *financial* benefits, in more discreet but sustainable fashion, could be obtained from working with indigenous populations on the development of biodiversity initiatives, ecotourism, archaeotourism, and indigenous arts and crafts programs that would benefit local and national economies.

Put into a historical context, current resistance to indigenous IP rights equates with the same suspicion which led the British Empire to forbid traditional rituals such as the potlatch, viewed as an incongruent waste of riches "not befit to British subjects," as it was put at the time. To put it in today's perspective, we can see the same resistance to indigenous rights and knowledges in the building of pipelines that cut through pristine forests, waterways, and ancestral lands of British Columbia and the United States. The lack of long-term vision toward ecological and cultural issues stems from a short-term dominant market economy focus, with limited financial benefits and significant risks for the very society at large.

Recently, in contested situations where it is too time-consuming or expensive for indigenous populations to fight for their IP rights in the courts, many groups are turning to the development of cultural protocols as nonlegal means of protecting cultural landscapes, knowledge systems, and intellectual properties. Cultural protocols are sets of guidelines developed by indigenous communities with or without the involvement of outsiders (archaeologists, scientists, business people, and government officials) to increase cultural sensitivity and understanding of cultural traditions, landscapes, and/or biocultural resources. Increasingly, archaeologists are working with indigenous populations to develop cultural protocols and research protocols for the protection of sacred sites and TK (Newsom 2014). The goal is to acknowledge and protect indigenous IP while changing behaviors and attitudes among outsiders, ultimately benefitting indigenous populations and the society at large. Although protocols are often

non-binding, they provide a flexible mechanism for advancing indigenous populations interests in controlling access to tangible and intangible heritage while renegotiating unequal knowledge-sharing practices (Bannister 2009: 287; Torsen and Anderson 2010: 76).

The issue of indigenous IP is embedded in a long link of themes from the survival of ecosystems to the reproduction of cultural traditions. All the links are intertwined in the deeply ritual world vision of indigenous populations, and as such the very subsistence of pristine forest trickles down to the survival of those traditions. The historical context of the early twenty-first century is on the side of indigenous populations, but not without important obstacles to surmount.

Indigenous Knowledge and Traditional Knowledge

Margaret M. Bruchac
Department of Anthropology, University of Pennsylvania, Philadelphia, PA, USA

Introduction

Over time, Indigenous peoples around the world have preserved distinctive understandings, rooted in cultural experience, that guide relations among human, nonhuman, and other-than-human beings in specific ecosystems. These understandings and relations constitute a system broadly identified as Indigenous knowledge, also called traditional knowledge or aboriginal knowledge. Archaeologists conducting excavations in Indigenous locales may uncover physical evidence of Indigenous knowledge (e.g., artifacts, landscape modifications, ritual markers, stone carvings, faunal remains), but the meaning of this evidence may not be obvious to non-Indigenous or non-local investigators. Researchers can gain information and insight by consulting Indigenous traditions; these localized knowledges contain crucial information that can explain and contextualize scientific data. Archaeologists should, however, strive to avoid interference with esoteric knowledges, sacred sites, ritual landscapes, and cultural property. Research consultation with local Indigenous knowledge-bearers is recommended as a means to ensure ethical practice and avoid unnecessary harm to sensitive sites and practices.

Definition

Traditional Indigenous knowledge can be defined as a network of knowledges, beliefs, and traditions intended to preserve, communicate, and contextualize Indigenous relationships with culture and landscape over time. One might distinguish "knowledge" as factual data, "belief" as religious concepts, and "tradition" as practice, but these terms are often used imprecisely and

interchangeably to describe Indigenous epistemologies. Indigenous knowledges are conveyed formally and informally among kin groups and communities through social encounters, oral traditions, ritual practices, and other activities. They include oral narratives that recount human histories, cosmological observations and modes of reckoning time, symbolic and decorative modes of communication, techniques for planting and harvesting, hunting and gathering skills, specialized understandings of local ecosystems, and the manufacture of specialized tools and technologies (e.g., flint-knapping, hide tanning, pottery-making, and concocting medicinal remedies).

Indigenous communities have devised distinctive methods of encoding useful data within philosophies of thought and modes of activity that are linked to particular landscapes. This data includes geographical, genealogical, biological, and other evidence that maps human relations to flora and fauna, land and water, and supernatural forces. Knowledge is often passed on through regular Indigenous performances – including oral traditions, song, dance, and ceremony – that convey both literal and metaphorical truths about these relations. Skilled individuals and families are entrusted to maintain these traditions; some are specialists who protect esoteric knowledges. Although many aspects of traditional knowledge have been identified and recorded through ethnographic and ethnohistorical research, some are still unknown to outsiders.

Individual ethnic and tribal communities, in different regions of the world, have preserved different versions of traditional knowledges. While these knowledges might share some things in common, they do not comprise a single (or simple) tool kit. Indigenous knowledges can be envisioned as an hereditary system of learned awareness and skill that enables wisdom to be gained and tools to be constructed, as needed, from the materials at hand. These knowledges are rooted in a particular place or ecosystem, but they are not necessarily static or fixed. Religious knowledges, for example, are quite portable and can be used to mediate human encounters with ancestral spirits and other-than-human beings, wherever these encounters might take place.

Indigenous Knowledge and Traditional Knowledge, Fig. 1 Roger Paul (Passamaquoddy), shown constructing the frame for a Wampanoag *wetu* (shelter) beside the Penobscot River in Maine, during a Wabanaki Writers retreat in 2009. (Photograph by Margaret M. Bruchac)

Ecological knowledges are also portable, in that they call for reliance upon local resources and careful observations of the interactions between living beings and natural processes within an ecosystem (any ecosystem) to ensure human survival (Fig. 1).

Knowledge Keepers

Some traditional understandings are common knowledge, shared by all members of a tribal community, ethnic group, kin network, or family. Many of these are learned through phenomenological experience and everyday activities. More specialized types of information are preserved by gatekeepers (e.g., tribal leaders, ritual practitioners, medicine people) who have vested interests in, deep experience with, and long-standing connections to significant sites. Keepers of oral traditions are often carefully trained to link parts of traditional narratives to specific events and

locales, and cultural coherence is ensured by regular repetition (Vansina 1985). In Native American communities, these people are often selected as children and carefully trained up by elders. In Australian communities, there are gatekeepers identified as "Traditional Owners" who may inherit this role within a family line; it is their responsibility to monitor and mediate human interactions with the ancestral landscape (Smith and Wobst 2005). Among the Maori, specific categories of specialized, protected knowledges are entrusted only to select members of a group (Smith 2012). In general, Indigenous knowledge-keepers and traditional elders are afforded considerable respect in their home communities; in the academy, however, they have not yet gained the same degree of status afforded to scientific knowledge-keepers.

Traditional Ecological Knowledge

Traditional ecological knowledge (also called traditional Aboriginal knowledge) can be defined as practical applied Indigenous knowledge of the natural world. This is more than a mere collection of primitive survival tactics; it is a system of awareness that offers both moral guidelines and practical advice. Local practitioners conduct their activities (e.g., plant medicine, shelter construction, hunting skills, craft manufacture) using natural materials; they must rely upon intimate understandings of local flora and fauna to collect the necessary resources. Traditional ecological knowledges emerged from environmental understandings shaped over time by incremental learning (including trial and error and experimentation), and they crosscut the scientific disciplines of biology, botany, geography, and cosmology (Augustine 1997; Berkes 2012). Some evidence suggests Indigenous overuse of fragile environments, but in general (in the precolonial era), Indigenous peoples endeavored to maintain traditional landscapes. They did not depend upon large-scale resource extraction and development; instead, they maintained unique floral and faunal communities through measured harvests and ritual activities that emphasized reciprocity (Apffel-Marglin 2011). Among many Indigenous groups, proper attention to local spirits is believed to be an essential element of long-term lifeways (Berkes 2012; Smith 2012). The religious tenets of ecological awareness (identified as sacred ecology) were encoded in instructive narratives and dynamic interactions with local environments, intended to ensure long-term survival (Berkes 2012: 219). Human health was a natural by-product of environmental health.

Stephen Augustine (*Mi'kmaq*) identifies traditional knowledge as a system that derived from the survival tactics that Indigenous peoples perfected over generations, preserved in collective memory and community teachings:

> This knowledge is exercised within the context of the social values and philosophies of the tribe. . .The fact that Native science is not fragmented into specialized compartments does not mean that it is not based on rational thinking, but that it is based on the belief that all things are connected and must be considered within the context of that interrelationship. (Augustine 1997: 1)

Gregory Cajete (*Tewa*) identifies this expansive mapping of knowledge as "Native science":

> Native science is the collective heritage of human experience with the natural world; in its most essential form, it is a map of natural reality drawn from the experience of thousands of human generations. It has given rise to the diversity of human technologies. . .in profound ways Native science can be said to be "inclusive" of modern science, although most Western scientists would go to great lengths to deny such inclusivity. (Cajete 2000: 3)

Traditional ecological knowledge, as a system, links sophisticated philosophies with practical measures as a means to mediate and moderate human interactions with ancestral landscapes. Some of the archaeological evidence from remote areas, where subsistence lifeways are the norm, suggests ancient continuities with the far distant past (see discussions of *Dene, Inuit*, and *Gwich'in* archaeology in Nicholas and Andrews 1997). Some ancient Indigenous stewardship practices appear to be equivalent with (if not superior to) modern conservation approaches (Nicholas and Andrews 1997; Apffel-Marglin 2011; Sillar and Fforde 2005).

Traditional ecological knowledges can inform everyday and ritual activities, in public and private venues. Some ritualized activities aim to

combine the knowledge and phenomenological experiences of multiple individuals for maximum effect. For example, in preparation for hunting, individuals may prepare their tools in a traditional location. The movements of the stars, measured by means of standing stones, may be used to predict the appropriate time and season to hunt. Traditional knowledge-bearers may utilize forms of divination, and a group might join together in dance to call the game. The products of the hunt may be selectively offered as reciprocal gifts to the forest or ritually shared at a community feast. The people who engage in these activities are not naively requesting favor from unseen forces; their actions are guaranteed success only if participants are keenly aware of the relevant ecological data (e.g., season, weather conditions, and general health of animal populations) before they begin. Evidence of these activities, in markers left on the landscape – piles of debitage, stone carvings, dance circles, and bone collections – may be encountered in later archaeological investigations (Fig. 2).

The precepts of traditional ecological knowledge can thus provide context and explanations for artifacts, site modifications, and evidence that might otherwise appear mysterious. As examples, consider two geographically different cases: Inuit hunters in the Arctic, who learn to respect the potential animacy (and inherent danger) of certain weapons and tools in an extreme climate; and medicinal practitioners in the Amazon rainforest, who develop exquisite senses of smell to distinguish among many different varieties of potentially poisonous plants. One might encounter archaeological remains reflecting these different knowledges: a tool scratched with symbols and a bundle of leaves. In their time, these distinct regional knowledges shaped the circumstances of survival; in our time, an awareness of these knowledges provides a crucial framework that situates and explains these people from the past.

Indigenous Knowledge and Traditional Knowledge, Fig. 2 Maritime archaic toggling harpoon point, housed in the collections of Memorial University, St. John's, Newfoundland, Canada. (Photograph by Margaret M. Bruchac)

In summary, traditional ecological knowledges include sophisticated site-specific and culture-specific instructions, embedded in the landscape and evidenced in unique skill sets, activities, and localized knowledges. If followed properly, these instructions are intended to ensure both short-term survival and long-term human health, community sustainability, and preservation of unique ecosystems (Apffel-Marglin 2011; Berkes 2012).

Oral Traditions

Oral traditions, whether communicated as historical narratives or mythical stories, constitute a form of traditional knowledge that can teach, carry, and reinforce other knowledges. Among Indigenous groups, oral traditions serve as the collective memories of ethnic, tribal, and kinship groups, a formal "corpus relating to the whole society" (Vansina 1985: 19). Oral traditions can blur the boundaries of narrative and performance in that they are both product and process, object, and experience. Although they may be characterized as fragile or malleable, these traditions are not simple hearsay or personal reminiscence; they are community memories, regularly recounted and periodically verified by knowledgeable elders.

Indigenous oral traditions often contain insightful explanations that focus on details: origin stories referencing natural and constructed features of the landscape, descriptions of the beings that inhabit this landscape, articulations of the reciprocal relations among these beings, and traditional beliefs that guide human interactions with place. Oral traditions can also include supernatural data: stories of encounters between

human and nonhuman beings in the distant past, messages delivered by animal intelligences, and spiritual visions and transformations (Cajete 2000; Bruchac 2005; Vizenor 2008). Some of the most ancient oral traditions record the actions of other-than-human beings who moved glaciers, rivers, and rocks, actively sculpting the Indigenous homeland. Some of the more recent ones explain distinctive place names that map and mark human geographies.

This information is typically passed on through acts of storytelling that are both literal and metaphorical, as they verbally reconstruct connections with the past (Bruchac 2005; Johnson 2007; Vizenor 2008). As Gerald Vizenor (*Anishinaabe*) articulates it, oral traditions in the hands of a skilled teller – a storier – can evoke elemental realizations:

> Native storiers of survivance are prompted by natural reason, by a consciousness and sense of incontestable presence that arises from experiences in the natural world, by the turn of the seasons, by sudden storms, by migration of cranes. . .by the favor of spirits in the water, rimy sumac, wild rice, thunder in the ice, bear, beaver, and faces in the stone. (Vizenor 2008: 11)

"Survivance" is more than mere survival; it is the active continuation of traditions that preserve the knowledges of these connections, including regular discourse with the ancestors to maintain a conscious "sense of presence over absence" (Vizenor 2008: 1).

Indigenous peoples may combine the narration of these traditions with other activities and symbols – ritual practice, dance, music, art, rock carvings, and mock combat – that ritually reenact or engage with ancestral beings or other creatures. Since many of these characters are represented in symbols or totems, archaeologists should familiarize themselves with kin groups and social markings of the population under study. Particular plots, characters, symbols, or other elements of traditional narratives may appear in ethnohistorical records that can shed light on archaeological remains (Bruchac 2005).

In Native American contexts, some individuals were destined from birth to become oral tradition-keepers, historians, and interpreters (Vizenor 2008: 12). In African communities, *griots* learned to recount geo-biographical narratives that recorded the lineage of key family groups and the length of residence in particular regions (see, e.g., discussions of Kenya and other African locales in Sefa Die et al. 2000). Oral traditions may speak of a particular family, lineage, language, or region or serve as markers of distinct Indigenous identities. From the colonial era to the present, oral traditions have also been employed as a means of identification and a form of resistance to colonial domination (Bruchac 2005; Johnson 2007; Vizenor 2008).

Oral traditions can have both practical and ritual aspects. On a practical level, Indigenous peoples have developed technologies that enable successful hunting and gathering. Yet, they recognize that animals, birds, and other beings have agency and traditions of their own. They expect to interact with these beings not only in the flesh but also through dreaming and ritual encounters (Apffel-Marglin 2011; Augustine 1997; Johnson 2007). Ritual activities provide a means of communicating with elemental spirits and worldly beings that have intelligences of their own (Apffel-Marglin 2011). Narratives of these encounters remind us that human relationships are inextricably intertwined with these beings and places.

Oral traditions, as products of human expression, may seem too ephemeral in locales where Indigenous agents are absent or silent. Yet, as a potential source of data, they should not be overlooked. Even when collected at a distance in time and space, local stories may still contain crucial data (e.g., site descriptions, explanations of practices, memories of social activities) that can map and mark a significant Indigenous site (Bruchac 2005).

Historical Background

Indigenous knowledges that predate colonialism were once regarded as primitive and unsophisticated; this cultural bias historically obscured both the structure and practice of these knowledges. Western practitioners posed a serious threat to

the integrity of Indigenous cultural traditions and territory, by regarding them as public scientific property. Archaeologists conducted investigations in destructive and ethically questionable ways. The damage included desecration of burial places, theft of cultural property, imposition of nationalist ideologies, interference with traditional activities, damage to local ecosystems, misrepresentations in museums, and general disrespect for Indigenous culture and property.

During the early years of archaeology, scientists were largely unaware of the validity of Indigenous knowledges, and intellectual exchanges between Indigenous and European knowledge-bearers were less than ideal. Indigenous peoples were largely treated as objectified subjects rather than participatory colleagues. Indigenous beliefs and traditions were regarded as religious superstitions when compared to both imperialist ideologies and larger organized religious movements. In North and South America, Australia, and New Zealand, Indigenous peoples were politically disempowered and living in a hostile atmosphere that made it difficult for traditional communities to maintain cohesion. Among the Maori, colonization directly interfered with the authority of traditional leaders and traditional knowledge, stripping away Maori control of their land and destiny (Smith 2012: 175).

Broadly speaking, all human knowledges are rooted in traditions passed on from one generation to the next, one community to another. In this regard, scientific approaches to archaeology could be considered a body of traditions that emerged from the distinctive social relations and exercises of power that developed in the environments of modern European academies. Within those academies, a mode of research was devised – the scientific method – that is prized for its presumed objectivity. The data collected is, however, catalogued and classified in ways that are somewhat detached from practical and sensory experience (Apffel-Marglin 2011; Smith 2012). Scientific models of thinking and organizing rely upon disciplinary divisions that segregate the natural world and products of human experience into disparate parts that do not reflect their places of origin (e.g., the use of Latin names for flora and fauna). Indigenous knowledges, by comparison, are inherently holistic and integrative, being rooted in sensory awareness and human experience of the complex relationships among multiple organisms in distinct ecosystems (Augustine 1997; Apffel-Marglin 2011; Smith 2012). Indigenous knowledge is not wholly unscientific, and concepts of "science" and "tradition" need not stand in opposition, since these are potentially complementary ways of organizing human understandings and interactions with the natural world.

For much of the nineteenth and twentieth centuries, anthropological studies of Indigenous knowledge largely focused on data that was useful to Western scientists. Ethnographic studies recorded biological identifications, hunting activities, naming practices, and linguistic structure as discrete bodies of data, without full consideration for the Indigenous philosophies that guided complex relationships among these forms of knowledge. During the early twentieth century, Native American individuals often served as informants and assistants at archaeological sites, but the relations between these individuals and the actual keepers of sacred knowledges are still open to question. Archaeological sites were particularly vulnerable to pot-hunting by amateurs (and some professionals) who disarticulated remains and removed cultural objects in the search for valuable specimens. These interferences damaged the integrity of sites and destroyed some of the evidence of Indigenous knowledges. As archaeologists moved to professionalize, national organizations pressed for legislation to protect the scientific value of Indigenous sites (e.g., the American Antiquities Act of 1905). Despite this effort, Indigenous consultation was not routine in the practice of archaeology until human rights issues came to the fore in the 1970s.

Key Issues/Current Debates

The fraught relationships between Indigenous peoples and archaeologists have shifted dramatically in recent decades, as a direct result of increasing attention to the ethics of practice and the inclusion of Indigenous people as research

partners (Nicholas and Andrews 1997; Smith and Wobst 2005; Schmidt 2009; Nicholas 2010). Practitioners of Indigenous archaeologies have often insisted that Indigenous knowledges be placed foremost when excavating Indigenous sites. Indigenous activists have also called for corrections to the many distortions of oral traditions and local knowledges that have influenced both public views of the Indigenous past and Indigenous views of themselves (Nicholas 2010; Smith 2012). As Linda Tuhiwai Smith (*Maori*) explains, these distortions are ideologically laden with colonial influences and have trapped people within a vision that "does not connect with either our oral traditions or our lived reality" (Smith 2012: 172).

In some regions, Indigenous people are exerting influence as sovereign nations to challenge the presumed exclusivity of state control and scientific ownership of heritage. Archaeologists can no longer assume sole authority in the field, and they should be prepared to encounter and negotiate potential disputes, not only over the ownership of sites and materials, but over the application of differing forms of knowledge (Smith and Wobst 2005; Atalay 2012). Indigenous ecological knowledges are likely to be called out as evidence in disputes over development or archaeological research in sensitive sites.

Among Native American and First Nations people in the United States and Canada, the continuation of traditional practices (e.g., ritual activities, seasonal hunts and harvests) may provoke conflicts with state and national conservation agencies and policies. Conservationists typically privilege romantic visions of uninhabited wilderness, rather than Indigenous visions of sustainable hunting, fishing, and harvesting (Apffel-Marglin 2011: 23). South American Indigenous activists face similar struggles in protecting traditional landscapes and practices. Traditional sites need protection and verification (which can sometimes be provided by archaeological surveys), but exposure may invite cultural and economic exploitation (bio-prospecting, bio-piracy, tourism, development). There is also the risk that exposure and development may interfere with the delicate balance of natural world forces (weather, water, climate, spirits) that ensure community safety (Apffel-Marglin 2011).

In recent decades, there has been considerably more awareness of Indigenous knowledge and more effort to ensure community involvement (Sillar and Fforde 2005; Menzies 2006; Atalay 2012). Traditional knowledges have informed archaeological studies of Indigenous religions, rock art, ritual, and sacred landscapes, improving the accuracy and complexity of these fields of study (Berkes 2012). Archaeological evidence of sustainable ancient practices not only testifies to long-term Indigenous habitation; it can also inform future policies in cultural resource management (Nicholas and Andrews 1997).

In some cases, however, the stereotypes (e.g., the paradigm of simplistic practice) persist, obscuring the evidence of subtle yet significant activities (Apffel-Marglin 2011). Oral traditions that record the details of sacred landscapes and ceremonial complexes may be missed by scientists in search of more recognizable evidence of human constructions. In the Andes, for example, channels constructed for the ritual conveyance of water spirits may be misunderstood as simple irrigation lines (Apffel-Marglin 2011). In Aboriginal Australia, cultural landscapes with minimal modification that house potent spirits and inspire instructive dreamings (see examples of *Barunga* and *Ngarrindjeri* lands in Smith and Wobst 2005) may not be recognized by outsiders as sacred.

As decolonizing scholars have noted (e.g., Augustine 1997; Smith and Wobst 2005; Nicholas 2010; Apffel-Marglin 2011; Smith 2012), the inclusion of Indigenous knowledge is not without controversy. Critics have questioned the veracity of Indigenous knowledges, challenged the qualifications of community experts with no apparent scientific training, and questioned the degree to which Indigenous peoples should be allowed to exert control over scientific research. Some wonder whether knowledges indigenous to one locale have any usefulness outside of that limited sphere (Ellen et al. 2000: 17). These concerns suggest

that Indigenous knowledges deserve closer study and better analysis. Anthropological and Indigenous scholars are addressing these concerns by codifying the tenets of Indigenous knowledge (e.g., Cajete 2000; Sefa Die et al. 2000; Smith and Wobst 2005; Berkes 2012; Smith 2012). They are also demonstrating that, in many cases, scientific knowledges can be expanded and improved through articulations with the perspectives and substance of Indigenous knowledges.

International Perspectives

In the postcolonial era, traditional knowledges are providing more than just explanations for past practices; they are informing many of the new protocols and agreements designed to govern the protection of Indigenous natural resources, cultural knowledge, and intellectual property. Not surprisingly, the new level of respect afforded to traditional knowledges roughly parallels the increase in collaborative Indigenous archaeologies. The protection of Indigenous rights (including guaranteed access to traditional landscapes and more conscientious cultural resource management) is now a crucial area of concern in international environmental law (Ellen et al. 2000; von Lewinski 2004; Menzies 2006). Concepts of intellectual property have been extended to include oral traditions, folklore, ecological knowledge, Indigenous languages, and traditional names.

In diverse locales (e.g., forest management in India, rubber production in South America, controlled fires in the Philippines), state officials are now relying upon Indigenous peoples to use traditional knowledges to identify and prevent future environmental threats (Ellen et al. 2000). In Latin America, many Indigenous peoples are exerting local knowledges as a means of reinterpreting the past and reclaiming control of ancient landscapes. In Amazonia, Bolivia, Colombia, Mesoamerica, and elsewhere, marginalized communities are collaborating with archaeologists to reassert their identities and reframe problematic state representations of their past (Gnecco and Ayala 2011). This suggests the need for a wholesale decolonizing of knowledge while rethinking our relationships with natural phenomena (Gnecco and Ayala 2011: 34).

Efforts in some regions have been more collaborative than others. In Canada, mainstream scientists have reached out to Aboriginal knowledge-keepers and First Nations tribal leaders to develop joint strategies to address climate change, habitat loss, and other damages caused by unchecked resource extraction and modern development. Both Indigenous and non-Indigenous communities stand to benefit from efforts that encourage sustainable use of local resources. In the Aboriginal Provinces of *Nunavut* and *Nunatsiavut*, for example, governmental agencies such as the Renewable Resources Division strive to develop policies that deliberately integrate Indigenous and scientific approaches to site preservation and wildlife conservation. Traditional landscapes are recognized as potentially fragile ecosystems, but they are also seen as living homelands for Aboriginal people who can be trusted to continue their traditional lifeways (including seasonal harvests and hunting) in a responsible manner that considers the health of future generations.

In recent decades, as a direct result of increased political engagement with Indigenous communities around the world, states and institutions have devised protocols to mediate relations among Indigenous peoples and scientists. The 1991 World Archaeological Congress code of ethics, for example, unambiguously acknowledges Indigenous peoples as the originators and owners of their traditional knowledges and cultural heritage (World Archaeological Congress 1991). The United Nations' *Declaration on the Rights of Indigenous Peoples*, adopted by the General Assembly on September 13, 2007, recognizes Indigenous ownership and validates traditional practices as contributors to "sustainable and equitable development and proper management of the environment" (United Nations 2008). Articles 11 and 31 identity these rights as follows:

> *Article 11.*
> 1. Indigenous peoples have the right to practice and revitalize their cultural traditions and customs. This includes the right to maintain, protect and develop the past, present and future manifestations of their cultures, such as archaeological and historical sites, artefacts, designs, ceremonies, technologies. . .
> *Article 31.*
> 1. Indigenous peoples have the right to maintain, control, protect and develop their cultural heritage, traditional knowledge and traditional cultural expressions, as well as the manifestations of their sciences, technologies and cultures, including human and genetic resources, seeds, medicines, knowledge of the properties of fauna and flora, oral traditions, literatures, designs, sports and traditional games and visual and performing arts. They also have the right to maintain, control, protect and develop their intellectual property over such cultural heritage, traditional knowledge, and traditional cultural expressions.

The Declaration also indicates that states are expected to provide restitution in instances where traditional culture and cultural manifestations have been taken without consent (United Nations 2008).

In Oceania and in the Americas, tribal leaders and tradition-bearers are reaching out to non-Indigenous peoples (including the scientific community and state agents), offering to share traditional knowledges to ensure mutual survival (see examples in Smith and Wobst 2005; Nicholas 2010; Atalay 2012; Smith 2012). As one such example, the *Haudenosaunee* (also known as the Six Nations Iroquois, a tribal confederacy in the northeastern United States and Canada) are re-awakening the agreement known as the "Two-Row Wampum." This diplomatic tradition invites two disparate cultures to coexist, side by side, without undue interference with one another. This ideal parallels some of the current efforts to integrate scientific and Indigenous knowledge. Caution is still needed, however, since archaeological applications of Indigenous knowledge (when used to locate sensitive areas, identify material culture, or map future developments) should be conducted in ways that protect the security of traditional landscapes and lifeways and avoid further damage to the Indigenous (Fig. 3).

Future Directions

Archaeologists have much to gain from recognizing the data and philosophies preserved within Indigenous traditional knowledge. Oral traditions can preserve records of ancient landscapes, and traditional ecological knowledges can explain human interactions with those landscapes. Wisdom gained in one locale may be used to interpret a related locale or to articulate linkages among past, present, and future generations. Indigenous ways of knowing are not, however, static fossils or reinvented memories. Despite the damage (and, in some cases, outright destruction) caused to Indigenous ecosystems and cultures by European colonization, many traditional practices

Indigenous Knowledge and Traditional Knowledge, Fig. 3 Peter Jemison (Seneca), tribal Faithkeeper and member of the Haudenosaunee Standing Committee on Burial Rules and Regulations, rolling up a modern version of the traditional Two-Row Wampum belt. (Photograph by Margaret M. Bruchac)

have persisted with a surprising degree of coherence (e.g., Augustine 1997; Apffel-Marglin 2011; Smith 2012). A considerable volume of data has been retained within Indigenous languages and philosophies. Indigenous peoples have also devised modern applications for traditional knowledge in the wake of colonization, by utilizing new resources (including manufactured and recycled materials) to produce traditional tools and crafts. Indigenous knowledges that emphasize experiential awareness can be helpful in multiple settings, since they readily allow for the incorporation of new data in response to new environments.

Indigenous people are increasingly being recognized, not just as cultural informants or site monitors, but as intellectual partners in the archaeological enterprise. Dozens of Indigenous people have become professional archaeologists (some of their work can be glimpsed in Smith and Wobst 2005; Schmidt 2009; Nicholas 2010). Their collective insistence upon collaboration, consultation, and respect for cultural tradition (reinforced by new legal protocols) has altered the routine practice of archaeology among the Indigenous and promises to inspire better understandings (e.g., Schmidt 2009; Nicholas 2010; Gnecco and Ayala 2011; Atalay 2012). The insights that emerge from these collaborations will continue to inform, expand, and complicate scientific understandings of the Indigenous past and present.

Indigenous Method and Theory in Archaeology

Paulette F. Steeves
Department of History and Philosophy, Algoma University, Sault St Marie, ON, Canada
Mount Allison University, Sackville, NB, Canada

State of Knowledge and Current Debates

Indigenous method and theory (IMT) in archaeology, carried out by Indigenous scholars and communities, is an act of reclaiming, revivance, and retelling, weaving Indigenous knowledge into discussions of Indigenous histories. IMT foregrounds Indigenous identities and empowers Indigenous communities, when Indigenous scholars and communities are in power and control of archaeological design and interpretations. IMT in archaeology weaves Indigenous knowledge through sacred sites, stories ancestors left on the land, and creates a richer more informed view of the Indigenous past. IMT recognizes Indigenous elders, storytellers, and community scholars as knowledge holders (Wilson 2007a, 325) that are the center of community histories, rather than informants who are outside the processes of knowledge production.

Indigenous archaeology has been described as archaeology with, for, and by, Indigenous people (Atalay 2006, 283). The differences between, with and for, and by Indigenous people are critical to Indigenous people and society in general. Not all archaeological projects with, and for, Indigenous communities, or by Indigenous archaeologists and communities are framed in IMT.

Archaeology for and with Indigenous people is a place of weaving Indigenous knowledge, oral traditions, and respect and relationality into archaeological research and discussions. Archaeology projects with and for Indigenous communities may or may not include Indigenous cultural practices and ceremonies, depending on the leadership and design of the archaeological project.

It is important to remember, however, where IMT springs from. It springs from centuries of

Indigenous ways of knowing, being, and doing; it springs from centuries long oppression, and from revival and reclamation of humanity and identity. For many Indigenous scholars who brought IMT into Western academies, it grew from powerful forms of resistance, from counter stories reviving civilized humanities from a dehumanized past. Linda Smith (1999, 4) argued: "The past our stories local and global, the present our communities, cultures, languages and social practices all may be spaces of marginalization, but they have also become spaces of resistance and hope."

Archaeology by Indigenous people is a political act (Tur et al. 2010) of reclaiming voice, sovereignty, humanities, identities, places, intellects, and spirituality. As Smith (1999) argued, reclaiming history is a critical and essential aspect of decolonization. To understand decolonization, it is imperative to understand historical and ongoing colonization. This is a starting place for anyone seeking to carry out research as ceremony framed in IMT. There is now a rich body of literature authored by Indigenous scholars, to inform our understanding of paths to decolonization, and the important differences in research and archaeology for and with Indigenous communities, and archaeology by Indigenous scholars and communities.

Archaeology framed in IMT acknowledges archaeological sites as sacred spaces (Parrish et al. 2000, 84). Land, cultural sites, and material (artifacts and ecofacts) are sacred and carry spiritual and cultural meanings (Atalay 2006, 282). In a collaborative archaeological project with the Kashaya Pomo community in California, cultural protocols were followed by archaeologists, students, and community members while working at the Metini Village site during a field school class taught by Kashaya Pomo elders and tribal scholars, as well as archaeologists from the State Park and University of California Berkeley.

Parrish et al. (2000, 84) discussed the need for an understanding of Kashaya Pomo negotiation of sacredness central to Kashaya Pomo problem solving within human and spiritual landscapes. Research by Indigenous archaeologists and communities, framed in IMT, where Indigenous people are in control of the design and discussions have been discussed as situated along paths leading to self-determination and sovereignty (Steeves 2015b, 4). It is most often, if not always, a political act of resistance and rhetorical sovereignty. It is a reclaiming and reviving of Indigenous ways of knowing, being, and doing. It is a weaving of knowledge, oral traditions, and stories on the land (archaeology sites) that Indigenizes archaeology, the academy, and education.

In academic and community scholarship, all researchers tell stories no matter what theoretical or methodological frame they choose to apply, or how they report their research findings. However, depending on the method and theory that the research is framed in, there is a great difference in the telling of stories. Indigenous scholars often present their research as storytelling; this reflects where the storytellers are in their lives (Wilson 2008, 6), "Location" "in Indigenous research, as in life, is a critical starting point" (Sinclair 2003, 122). In IMT, *Research is Ceremony* (Wilson 2008, 6) and is framed in respect, relationality, and reciprocity. In processes of resistance, resurgence, and reclamation, stories lay the foundational framework for "Indigenous sovereignty and the reclamation of material ground" (Sium and Ritskes 2013, 111). In narratives of research, Indigenous scholars framing their research through IMT most often begin a research story by sharing their place in life and in the research (Steeves 2015b; Yellowhorn 2002; Reimer 2012). In sharing details of who they are, they claim their ancestry, acknowledge their ancestors, and declare their positions as researchers and authors. They intentionally locate themselves as Indigenous people first and researchers second; this presents the ways of being, knowing, and doing that their research is based in. This allows others to be informed of relations that might exist and their research as relational and applied. In providing this background and these details, they are "identifying, defining, and describing the elements of Indigenist research" (Irabinna Rigney 1997; Martin-Booran Mirraboopa 2003, 3).

Indigenous ways of knowing, and sharing research results are very diverse. In Australia, Aboriginal people use the term "yarning"; it is a storytelling, a way of sharing information, passing

on histories and knowledge, and a way of connecting with the Nyoongah culture (Bessarab and Ng'andu 2010, 38). Yarning is an Aboriginal way of telling and sharing stories (Terszack 2008, 90). It is not a one-way process but reciprocal and mutual (Bessarab and Ng'andu 2010, 38). In working with and for Indigenous people, it is important that researchers become knowledgeable regarding Indigenous communities languages and terminology used to share knowledge. Indigenous understanding considers and links the physical, human, and sacred worlds (Institute for Aboriginal Development 2000); this is a way of knowing that is foreign to most Western researchers and epistemologies. An informed understanding of how Indigenous people view, understand, and discuss their worlds is central to research and discussions of Indigenous histories, lands, and oral traditions (Mihesuah 1998). Gegeo and Watson-Gegeo 2001 discussed applications of Indigenous epistemologies to research projects in the Solomon Islands.

> From the Kwara'ae standpoint, indigenous ways of creating knowledge are part of the kula 'point, part, place' system or mosaic of cultural knowledge that includes the whole person, family, kin group, and society (see Watson-Gegeo and White 1990). As a concept, indigenous epistemology focuses on the process through which knowledge is constructed and validated by a cultural group, and the role of that process in shaping thinking and behavior. (Gegeo and Watson-Gegeo 2001, 58)

Indigenous scholars have consistently discussed research framed within Indigenous methodologies as counter stories, and powerful forms of resistance (Brown and Strega 2005; Smith 1999, 2). Stephanie Kennedy specifically explored Indigenous archeology as a form of resistance to dominant Western science (Kennedy 2010, 5). Indigenous archaeology by Indigenous communities seeks to carry out respectful research, to restore knowledge of places that have been historically distorted, erased, and denied in anthropological knowledge production (Gnecco and Ayala 2011, 53). Indigenous methodologies create a site for the critical analysis of the intersections of Indigeneity, gender, race, colonialism, and class (Byrd 2009, 15). Angela Wilson (2004, 359) stated that Indigenous knowledge recovery is an Anticolonial process. It is a project that "gains momentum from the anguish of the loss of what was and the determined hope for what will be" (Wilson 2004, 359). It springs from centuries of "colonialism's efforts to methodologically eradicate Indigenous ways of knowing, being, and interacting with the cosmos" (Gnecco and Ayala 2011, 60). The recovery of indigenous histories works to recreate and revalue, that which has been erased, denied, and denigrated, as it measures the silence of academics (Gnecco and Ayala 2011, 25).

Margaret Kovach (2005) offers the following as an explanation of what represents an Indigenous epistemology (26):

> It includes a way of knowing that is fluid (Little Bear 2000) and experiential, derived from teaching transmitted from generation to generation by storytelling… It emerges from traditional languages emphasizing verbs, not nouns (Cajete 2000). It involves a knowing within the subconscious that is garnered through dreams and visions (Castellano 1999). It is the knowledge that is both intuitive and quiet. Indigenous ways of knowing arise with the human world, the spirit, and the inanimate entities of the echo system (Battiste and Henderson 2000). Indigenous ways of knowing encompass the spirit of collectivity, reciprocity, and respect (Wilson 2001). These ways of knowing are both cerebral and heartfelt. As the elders say, "if you have important things to say speak from the heart." (Kovach 2005, 27)

Archaeology in the Western Hemisphere (the Americas) developed and grew from Indigenous places on the land. Indigenous places have been highly contested since ships first sailed from the Eastern Hemisphere seeking new lands and all they held. Scholars often use the term, place; it is their rhetorical sovereignty, their right to discuss lands, places, and people as they choose. Indigenous as a place or identity is not essentializing. As argued by McGhee (2008, 584), it is an acknowledgment of Indigenous peoples presence on the land; it is a claiming and reclaiming, and a right of rhetorical sovereignty to discuss ancestral areas as Indigenous places. In a reply to McGhees' discussion of Indigenous archaeology, as essentialist Western and Indigenous scholars (Colwell-Chanthaphonh et al. 2010) critiqued McGhee's discussion:

> Indigenous rights are not founded on essentialist imaginings. Rather, the legacies of colonialism, sociopolitical context of scientific inquiry, and insights of traditional knowledge provide a strong foundation for collaborative and community-based archaeology projects that include Indigenous peoples. (Colwell-Chanthaphonh et al. 2010.

> Anyone who has visited more than one Indigenous community will soon realize that in spite of what acculturationists have written about the perpetually vanishing savage (a position that merely enhances the position of researcher as conservator), many Indigenous Peoples continue to exhibit, maintain and assert fundamentally different values attitudes and beliefs than our Western contemporaries. (Wilcox 2010, 225)

Wilcox addressed issues of Indigenous erasure in acknowledging Western archaeological assumptions of the perpetually vanishing savage. Western archaeological discussions have often described Indigenous communities as mysteriously disappearing from specific places or areas. Without the knowledge of contemporary Indigenous communities regarding their ancestors places on the land, communities and histories are erased, and links to the land cleaved through Eurocentic and uninformed assumptions. IMT with, by, and for Indigenous people works to re-link ancestral and descendant communities through a holistic body of knowledge and data. There may be many stories on the land (archaeology sites) that are not currently linked to a contemporary descendant communities. However, that in itself does not in any scientific or theoretical way support assumptions that entire communities mysteriously disappeared. In archaeology, we follow people's paths across places seeking to understand human movements across time and place. If we assumed that entire communities actually disappeared without leaving a trace, why would archaeologists seek to link people across time and place. People live and die in places; evidence of this is found across millions of years. It is not that entire communities just disappeared, but that we cannot find their stories on the land, for many reasons, lack of funding, lack of technology, lack of IMT, and Indigenous archaeology. In many if not all Indigenous worldviews and in IMT, respect and responsibility acknowledges Indigenous communities as having lived in, and often continuing to reside in specific places on the land in the physical and spiritual world (Rika-Heke 2010, 202).

Regarding Indigenous places, Basso discussed places in relation to people across time and space as practices as old as people and places.

> What do people make of places? The question is as old as people and places themselves as old as human attachments to portions of the earth. (Basso 1996, Xiii)

There are many Indigenous scholars across diverse fields of the academy working to reclaim and revive Indigenous knowledge, languages, and identities, to rewrite the past, present, and future. IMT is reviving and reclaiming by Indigenous people who have a first-hand experience of the impacts of colonization of their homelands, identities, and cultures. Indigenous research methodologies are those that enable and permit Indigenous researchers to be who they are while engaged actively as participants in research processes that create new knowledge and transform who they are, and where they are (Weber-Pillwax 2001, 174). IMT in archaeology brings the voices and memories of the people, to places on the land, linking ancestral knowledge to contemporary people Indigenous ways of being, doing, and knowing bring much-needed counter-discourses to a field of study known for its oversimplified and dehumanized views of the Indigenous past (LaRocque 2011, 4).

> Indigenous research is ceremony and must be respected as such. A ceremony according to Minnecunju Elder Lionel Kinunwa, is not just the period at the end of the sentence. It is the required process and preparation long before the event. It is, in Atkinson's (2002) translation, dairy, the many ways and forms, and levels of listening. It is in Martin's (2003) terminology, Way of Knowing, Way of Being, Ways of Doing, It is the knowing and respectful reinforcement that all things are related and connected. It is the voice of our ancestors that tells us when it is right and when it is not. Indigenous research is a life-changing ceremony. (Wilson 2008, 61)

Research framed in IMT is a praxis that weaves through institutional and public spaces to create social change. McGuire (2008, 3) argued that "Praxis becomes emancipatory when it advances

Indigenous Method and Theory in Archaeology, Table 1 Indigenous and Western sciences

TEK Indigenous sciences	Western science
Oral tradition	Written tradition
Holistic approach	Reductionist
Learned from observation and experience	Taught and learned: Mainly analytically
Environment as part of social and spiritual relationships	Hierarchical and compartmentalized organization
Based on cumulative, collective experience	Based on laws and theories
Mainly qualitative	Mainly quantitative
Data generated by resource users	Data collected by specialists or experts
Long time within one location	Short time-series over a large area
Integrated and applied to daily living and traditional subsistence practices	Hypothesis falsification and model

Compiled by Steeves 2015b

the interests of the marginalized and the oppressed against the interests of the dominant." Such social change addresses the past real-world consequences of colonial archaeology and addresses colonization in the present. Beyond a method or theory, it is drawn from a way of life, from centuries of living and being and respecting all clans, and the land.

A brief comparison of Indigenous and Western research methodologies highlights the importance of understanding the difference between the two, though there are also other methodologies and other ways of carrying out Western research that are not included here (Tables 1 and 2).

In discussing IMT, it is important to also briefly review what IMT is not. It is not researchers or academics whether Indigenous or non-Indigenous discussing Indigenous knowledge, culture, or ways of being, doing, or knowing. IMT is not Indigenous or non-Indigenous scholars discussing research through Western frames of thought. Being Indigenous does not automatically frame one's research and discussions in IMT (Tur et al. 2010). Including Indigenous knowledge or thought in a research project or paper is not IMT. It is not just about including the voices of Indigenous communities who are studied and researched; it is about applying principles of Indigenous cultural practices and ceremonies to research. Indigenous archaeology framed in IMT is focused on "finding ways to create counter-discourse that speak back to the power of colonialist and imperialist interpretations of the past" (Atalay 2006, 294); it is not simply interpreting the past.

Among Indigenous communities, a research project begins with and ends with ceremony, as Shawn Wilson (2001) so eloquently stated with prayers, dreaming, singing, and dancing for many cultural ways are woven throughout acts of respect for traditional ways of gathering knowledge. IMT is an intentional framing of research and discussions, through Indigenous ways of being, doing, and knowing, through *Research as Ceremony*. Shawn Wilson and other Indigenous scholars discuss the four bases of IMT as the 4 Rs.

Relationally- "An Indigenous paradigm comes from the fundamental belief that knowledge is relational, is shared with all creation, and therefore cannot be owned or discovered. Indigenous research methods should reflect these beliefs and the obligations they imply" (Wilson 2001).

Respect- All living things are respected and are related. In the Indigenous world, all beings have agency and equality humans, are but one member of many species with rights deserving of respect, and with the abilities of culture, language, and agency (Preston 1999, 36).

Reciprocity- If research is not done for a good reason to support or benefit our relations, we should not do it. Our focus is not first on the

research, but on what it will give to those we are working with, or for, or for a greater good (Weber-Pillwax 2001).

Responsibility- Indigenous researchers have a responsibility to all generations, past, present, and future, to carry out research in an ethical manner, respectfully as responsible for all our relations.

> Indigenous peoples' interests, knowledge, and experiences must be at the center of research methodologies and construction of knowledge about indigenous peoples. Lester-Irabinna Rigney (1999, 119). (Narungga Nation, Australia)

> Indigenous approaches to research on Indigenous issues are not meant to compete with, or replace, the Western research paradigm; rather challenge it and contribute to the body of knowledge of Indigenous peoples about themselves and for themselves, and for their own needs as people, rather than as objects of investigation. (Porsanger 2004)

For Indigenous researcher's empirical knowledge and informed understandings of oral traditions are crucial to research, as are cultural knowledge's, cultural protocols, and community guidance (Smith 1999, 15; Wilson 2008, 58). Eldon Yellowhorn (Blackfoot) highlighted the importance of cultural traditions in an *Internalist Archaeology* (Yellowhorn 2002, IV). Yellowhorn stated, "archaeological interpretations begin with a study of oral traditions, which are records of ancient history, cultural tradition motivates fieldwork" and, "appropriates the methods of archaeology to study local histories" (Yellowhorn 2002, IV).

> Roger Echo-Hawk stated:
>
> Archaeologists frequently say that the sites they excavate and the artifacts they recover can speak to us across the centuries. In oral traditions, we can hear the echoes of the actual voices of the people who made those artifacts and who were the original owners of the skeletons. As researchers explore the contribution to the history of oral traditions in Africa, Australia, and the Americas, it has become increasingly difficult to ignore arguments that historical information has been preserved through verbal means for great lengths of time. (Echo-Hawk 2000, 285)

Though not claiming to frame his discussion in Indigenous methodologies, Vine Deloria Jr. (1995) spoke clearly through Indigenous epistemologies and satirical, critical thought. His critique of archaeology in the Americas shook the field and moved the discipline toward reflective thought and new beginnings where IMT became a distinct possibility.

The impact of a colonial and Eurocentric archaeological knowledge production on Indigenous peoples has been discussed by a few archaeologists who recognize that the archaeological record used to interpret and construct the past has power in the present (McGuire 1992, 828; Smith and Wobst 2004b, 393).

> The relations amongst traditional knowledge, Native voices, and archaeological work are structured by inequalities that affect the lives and ongoing resistance of indigenous communities and emerging nations. This suggests that archaeological studies in Indian country should always be critical, confronting silences, building new approaches that are collaborative and grounded, and recovering counterfactual histories to challenge neocolonialist discourse. (Handsman 2003, 28)

Western archaeology has been discussed as an inherently political act (Jackson and Smith 2005, 329), one that often erased Indigenous humanity and agency. IMT by Indigenous scholars, and in some cases with and for Indigenous communities, is also a political act, one that re-claims Indigenous communities agency and self-determination. Indigenous or colonized communities reclaiming agency and self-determination are not just a political act; it is an important piece of healing or rehumanizing landscapes and protecting cultural and spiritual sites. Eduardo Duran (2006, 1) addresses the path of critical inquiry as one which leads to a liberation discourse, and new narratives of healing. Beyond a beginning of healing discourses, Duran reaches into the very heart of academia, and reminds us this is not just a healing for those impacted by colonial histories, critical scholarship of our own field is a path to liberating ourselves and the academy (Duran 2006, 1).

> The research we do as Indigenous people is a ceremony that allows us a raised level of consciousness and insight into our world. Let us go forward together with open minds and good hearts as we further take part in this ceremony. (Wilson 2008, 11)

Indigenous ways of telling stories may be woven metaphors linking minds, hearts, and histories to the land, and the land to the people. To understand IMT, you must first come to know the people, to understand the ongoing impacts of colonization (Tur et al. 2010), and what it is to have your history and humanity erased. Then you may begin to understand what IMT is, and where it has come from, and why it is so very pivotal to Indigenous resurgence, revival, and reclamation.

Indigenous communities and scholars who frame archaeological research in IMT, are not just gathering material evidence of their ancestors' histories on the land, they are gathering medicines for healing their communities. They are creating counter stories to archaeological narratives that disconnect them from their homelands, ancestors, and identities. Donald Julien et al. (2010, 165) discussed how the language used by Western scholars can alienate people from their lands and ancestors. Julien et al. (2010, 165) argued that language that alienates people from their ancestry and lands breaks their relationship to lands and ancestors and thus breaks their spirits as well. Julien et al. (2010), in community work at the Debert archaeological site in Eastern Canada, a project which has grown to include the Mi'kmaw community, stated:

> The Mi'kmaw set their highest priorities in understanding their culture and history, to bring healing to both the individual and the community. …. transferring cultural knowledge, language, and community histories to the next generation is critical to the health and wellbeing of individuals and communities. (Julien et al. 2010, 163)

IMT in academia is one flame of the Eighth Fire. It is one medicine in a bundle, a medicine of healing historical and intergenerational trauma. It is framed in cultural practices that are thousands of years old; it acknowledges, respects, and begins with ceremony. It weaves through stories and Indigenous ways of being, doing, and knowing held in hearts and on the land. Leanne Simpson (2008, 14) discussed an Anishinaabe prophecy, predictions which have foretold history since creation:

> The latter part of that prophecy relays that we are currently living in a time of the Seventh Fire, a time when, after a long period of colonialism and cultural loss, a new people, the Oshkimaadiziig, emerge. It is the Oshkimaadiziig whose responsibilities involve reviving our language, philosophies, political and economic traditions, our ways of knowing, and our culture. The foremost responsibility of the "new people" is to pick up those things previous generations have left behind by nurturing relationships with Elders that have not "fallen asleep." Oshkimaadiziig are responsible for decolonizing, for rebuilding our nation, and for forging new relationships with other nations by returning to original Nishnaabeg visions of peace and justice. According to the prophecy, the work of the Oshkimaadiziig determines the outcome of the Eighth Fire, an eternal fire to be lit by all humans. It is an everlasting fire of peace, but its existence depends on our actions and choices today. In order for the Eighth Fire to be lit, settler society must also choose to change their ways, to decolonize their relationship with the land and with Indigenous nations, and to join us in building a sustainable future based upon mutual recognition, justice, and respect. (Simpson 2008, 14)

IMT in archaeology, and in all research, is carried out as ceremony and is orientated to addressing issues that remain critical to Indigenous communities, healing, emancipation, self-determination, and decolonization. Indigenous research is clearly focused on directions of decolonizing, re-writing, re-claiming, reviving, and self-determination (Wilson 2007a, 330) along paths of healing. To acknowledge connections between contemporary Indigenous people and ancient ancestral landscapes and to transfer Indigenous histories to the next generation is to acknowledge and support cultural continuity and healing (Steeves 2015b). There are thousands of Indigenous communities on a global scale. Thus, there may be many variations of IMT (Smith and Wobst 2004b, 393), with similar frames of respect, relationality, responsibility, and reciprocity, woven through cultural practices and storytelling.

Indigenous archaeology, or archaeology by, with, and for Indigenous communities, has become a way of reclaiming and reviving cultural practices and Indigenous knowledge in many colonized areas of the world. Though academia and archaeology still have a long way to go to create an archaeology that acknowledges the rights of Indigenous people, and is relevant to them, there are examples of decolonization and growth within the field. Norwegian

archaeologists working among the Saami have used oral histories, myths, and legends in understanding the past from a purely Saami perspective (Chirikure et al. 2008, 6; Damm 2005). For examples of archaeological projects within IMT, see further readings.

IMT starts within Indigenous oral traditions, cultural practices, community-centered research, and ceremony. For Indigenous communities, it is one path of many along ceremonies of healing and revivance. There are many reasons why Indigenous method and theory are important to both Indigenous and non-Indigenous scholars and communities, an understanding of alternatives to Western thought regarding Indigenous histories is pivotal education and to decolonizing the academy.

"Indigenous methodologies prompt Western traditions to engage in reflexive self-study, to consider a research paradigm outside the Western tradition that offers a systematic approach to understanding the world. It calls for the non-Indigenous scholar to adjourn disbelief and, in the pause, consider alternative possibilities" (Kovach 2009, 29).

It is important to re-write Indigenous histories from an informed Indigenous perspective (Byrd 2011, xxx). An Indigenous view of the past creates a dialog which forms the basis of an empowered identity from which Indigenous people can challenge historical erasures of communities, peoples, and places (Steeves 2015a). Indigenous knowledge, cultural practices, and histories are centered in a lived experience flowing across thousands of years of memories held in the land, stories, songs, art, and ways of being, doing, and knowing. Archaeology by, with, and for Indigenous communities framed in Indigenous methodologies, and carried out through Indigenous communities cultural protocol, creates a holistic and rich view of Indigenous communities across time and place.

Indigenous Peoples and the Challenges of Genetic/DNA Studies

Sheila M. van Holst Pellekaan[1] and Mark Dugay-Grist[2]
[1]School of Biotechnology and Biomolecular Sciences, University of New South Wales, Sydney, NSW, Australia
[2]Grist Archaeology Heritage Management, Frankston South, VIC, Australia

Introduction

All human societies have developed ways of explaining the natural world around them, resulting in different belief systems that also provide a framework for sociopolitical structures and physical and spiritual connections. Archaeology examines material evidence of the past, and archaeological methods have arisen through theoretical and technological science-based endeavor. Genetic analyses probe the essential molecules of organisms that are templates for life, presenting personal and societal challenges. Indigenous knowledge includes scientific knowledge acquired by experience and application to the needs and circumstances of communities that are not necessarily grounded in the ways of western science. Indigenous peoples have lived through recent histories of colonization while retaining much of their culture and belief systems which is a tribute to resilience, survival, and an indication that western-based science should not and does not always replace those belief systems. Indigenous perspectives from the living descendants of the first Australians serve to exemplify the contrast between traditional belief systems and the challenges presented by western science. The issues that arise are similar to those experienced by other indigenous peoples but also take on specific meaning for regional groups depending on their experience and exposure to the dominant culture of the colonizers.

The western scientific method of explaining the natural world is to propose ideas or hypotheses and test them by the acquisition of evidence that can be analyzed and evaluated. Using the methodologies of the time, data emerge, accumulate, and provide material for intellectual interpretations that in turn gives rise to new or revised hypotheses. These dynamic principles have become the hallmark of *western science*. Technological advances have arisen from scientific endeavor and, in turn, provide tools for the ongoing process of investigation. Technologies that allow biological investigation of living and past organisms have developed very quickly over the last 300 years. The scientific basis of *ancestry-related genetics research* is embedded in an evolutionary paradigm that assumes that all living organisms evolved over millions of years. That paradigm in itself is based on scientific evidence of the history of our planet derived from many disciplines, especially geology, paleontology, and chronology. Gene technology improvements have accelerated over the last 50 years, allowing detailed description of the essential building blocks of life, DNA, in living organisms and the genetic diversity that abounds within and between species. However, just how the vast, accumulating databases from DNA studies help us to know biological systems and how they react with environmental influences in time and space is only partly understood. The applications of genetic research may be directed at conservation biology, veterinary science, evolutionary biology, developments in primary industry, and, in the case of human genetic studies, forensic investigation, the probing of ancestral relationships and in medical research.

An indigenous perspective of the Australian past is drawn from a tradition of deep oral history and spiritual connection to country, language, traditional ties, and social structure. Among Aboriginal Australians, there is a commonly held view that ancestors originated in Australia; therefore, any alternative explanation of origin, including views held by different religions, presents a conflict. However, there is a growing acknowledgement and appreciation of western science within

the Australian Aboriginal community. The imposition of western scientific methodology provided different tools, so that a plethora of ethnographies and linguistic and archaeological studies eventuated that demanded evidence of human habitation and forced dates upon the story, not required for indigenous concepts of origin. Over the last 200 years, accumulated scientific information shows strong support for a very long human presence in Australia but not of an in situ origin, recognizing that Australian Aboriginal peoples are one of the oldest living cultures on earth outside sub-Saharan Africa. Genetic studies support archaeological evidence, demonstrating that anatomically modern humans were living in Australia, the world's largest island continent, while Neanderthals and ancient Asian peoples were in Europe, Asia, and islands to the north. Within the social milieu of Australia today, many Aboriginal and Torres Strait Islander people enjoy their heritage and reconcile it with knowledge acquired through science, while others find it difficult.

Over several decades, scholars have studied skeletons of Australian Aborigines and developed theories that have tested models of human evolution and at the same time created confusion for many indigenous people. In several instances, the skeletal remains of the Australian Aboriginal people have been at the center of the human evolutionary debate. Biological data collected from skeletal remains are deemed important in linking anatomically modern humans (AMH) to *Homo* lineages of the distant past and understanding how ancient peoples were dispersed throughout the globe. In more recent times, DNA analyses on both the living and the dead have also been used to inform us of the human evolutionary story, and this development has presented additional challenges. These DNA studies are for the most part controlled by western-based research. The technology that enables these studies has accelerated the accumulation of genetic data about skeletal material and living humans that impact on the lives of indigenous peoples who may not be ready to see beyond the perceived risks, to the benefits that may flow.

Are these contrasting approaches reconcilable? This entry reflects on the contribution made by science-based research about skeletal material from Australian Aboriginal people as well as DNA studies from the living and the insights that have been gained from the collected data. Importantly, the discussion includes an indigenous perspective that explores the understanding held by living Aboriginal people regarding their ancestors from a geographical region in southeastern Australia (Fig. 1). By so doing, we obtain a guide to an indigenous perception of the importance that these data hold for people. A particular concern is to address the challenges that genetic research has for Australian indigenous peoples in the context of multidisciplinary investigations of past peoples, their relationship with their ancestors and with contemporaneous neighboring groups, and their place among other people of the world. It is an area needing the input of Aboriginal and Torres Strait Islander Australians, and it is timely for these challenges to be discussed appropriately.

Definition

Indigenous peoples are those deemed to be the earliest (first) inhabitants of a geographic region and in the current global context, before the intrusion of recent incoming peoples (for Australia 1788).

Archaeology endeavors to recover the material remains of past and present populations and study and interpret the remains, the activities, and the cultural practices that relate to the people who were responsible for the items and/or belief systems.

Genetic/DNA studies examine the molecular structure of deoxyribonucleic acid (DNA), the molecule that provides a template for life (cross-reference). DNA is inherited over generations, for an individual from both parents (nuclear DNA) and also maternally (mitochondrial DNA). Studies of variation and patterns in DNA may be used to explore questions of past and living populations.

Indigenous Peoples and the Challenges of Genetic/DNA Studies, Fig. 1 The enlarged area shows the Murray-Darling region of southeastern Australia discussed in the text. Aboriginal Australians have been involved with western scientists in research that includes genetic, anthropological, archaeological, and linguistic studies. Details of those studies and many others from the Australian continent can be accessed through the references provided

Historical Background

Australia's archaeological record from many studies (see, e.g., Bowler et al. 1970; O'Connell and Allen 2004) set the scene for population genetics in the 1980s by showing the richness and diversity of the continent's habitation history. Discovered and studied skeletal material shows variation in morphology ranging from extremes of ruggedness to comparative "gracility" that has added to the debate about origins, namely, whether the extremes represent descent from different ancestors or whether they simply fall within the range of normal variation. Indigenous Australians, including indigenous archaeologists, also recognize the physical variation between peoples and are aware that morphological features of some Australian Aboriginal cranial material have attracted scholars from both sides of the academic divide. While understanding the two models that have been hotly debated for the greater part of the last 30 years or more, some indigenous scholars and respected Elders have come to hold the view that by using whatever technical tools available, benefit flows to indigenous people by helping nonindigenous people to understand the history, richness, and essence of "indigeneity." For Aboriginal and Torres Strait Islanders, the notion of ancestors coming from somewhere over the sea is not so removed from that derived from western science. How people got to Australia is one of the greatest journeys about men, women, and children of the ancient past venturing into new lands. Respect for both the traditional and contemporary views can coexist, so that an indigenous person can believe that use of techniques such as DNA analysis is of value and see it as a useful gift of the modern world. So in Australia today, indigenous opinions vary, some believing only that they originated in Australia while others think that their world is here in Australia and also believe in descent from a hominid cradle in Africa. In many ways, contemporary Australian Aboriginal society has been brought to life through these works, and DNA studies complement and enrich the continuing story. It will be through further research, including genetic studies, that the journey of Aboriginal Australians to the continent will be understood and hence contribute to the greater story of hominid movement around the globe.

The foundations for human ancestry-related genetic analyses were derived from population studies in many other species that demonstrated the remarkable heritability of genetic material and, once the structure of DNA became known, established sound methodologies for studying diversity within and between species. The earliest genetic evidence of the genus *Homo* (Cann et al. 1987) and many studies that followed supports the idea that humans evolved in Africa and spread throughout Eurasia before dispersing into all other parts of the populated world. Recent genetic evidence confirms previous work that supports the contention that Aboriginal Australians of today descend from the earliest humans to occupy Australia and therefore represent one of the oldest continuous populations outside Africa (van Holst Pellekaan 2011). The timing for human dispersals remains contentious. Genetic studies that include Aboriginal Australians are not representative of the whole continent but are valuable because they confirm the presence of very ancient Australian maternal lineages, some of which have ancestral connections with people from Papua New Guinea and others are Australian specific indicating that Australia was settled very early in the diasporation of modern humans (van Holst Pellekaan et al. 2010; van Holst Pellekaan 2011). Genetic signatures indicate that people may have entered at different parts of the northern shores around similar times, moved on, and then underwent a period of relative genetic isolation when sea levels rose. Importantly, some of the participants in these genetic studies belong to the Darling River region, part of a well-studied area that is useful to consider as an interface between western science and indigenous involvement, which has increased significantly in heritage management over the last two decades.

A Regional Study Area Example from Australia

By examining the experiences of a well-studied geographic region encompassing present-day northwest Victoria, western NSW, and South Australia (see Fig. 1), the impact of western science on the living descendants of the first Australians serves to illustrate how belief systems can accommodate different ways of explaining the world. The region is important, firstly, because early exploration of Australia resulted in valuable written observation and ethnographic records exemplified in Blandowski's work of 1841 (Allen 2010); secondly, archaeology has revealed and dated many sites (Ross 1981; Pardoe 1995; Grist 1995); and thirdly, human skeletal morphology and *genetic studies* have included participation from strong family lineage members (Pardoe 1995: 697; van Holst Pellekaan et al. 2010). These studies have served to demonstrate that the region was rich in resources during the Pleistocene and into the Holocene supporting many inhabitants. Soon after European colonization, around 1850, the occupants were from many language groups in the area whose descendants now identify as, for example, the Nyeri-Nyeri, Yitha-Yitha, Wemba-Wemba, Mutti-Mutti, Letyi-Letyi, Maraura or southern dialect of Paakintji, and linguistically more distantly related Nyemba. Hercus (2010) names three distinguishable language subgroups in the country around the Murray-Darling junction: the Kulin languages of Victoria, the Murray River languages, and the Paakintji or Darling River languages within which many related dialects have been identified, despite the losses resulting from colonization.

Explorers' observations from the 1830s (see also Hope 1998 and references therein) provided general observational reports about inhabitants of the broad region. Perhaps one of the most informative is the 1841 illustrated narrative by William Blandowski, some of which is recently republished (Allen 2010) and highly valued among people of the area. Reproductions of Blandowski's illustrations provide an extensive visual description of people, customs, and lifestyles. Blandowski showed the presence of fully developed hunter/gatherer societies with well-established boundaries between neighbors. It is important to understand that while specific names of Aboriginal people pictured are usually unknown, their regional and, in some cases, specific language affiliation (e.g., Nyeri-Nyeri) are acknowledged. For descendants of these people, this provides a personal link (Dugay-Grist 2010). For the Nyeri-Nyeri descendants who retain stories of named old people that have been handed

down over 200 years, a link between traditional stories and the present is strengthened, connecting to land, in turn to other country and their people. Despite the colonization experience, these links contribute to the conduct/management of lives today.

Archaeological richness abounds in the area along and to the east of the Darling River including sites at Lake Mungo and within the broader Willandra World Heritage Area. Dozens of scholars and indigenous people have been involved in working together after the discovery of Lake Mungo burials that have been variably estimated to be 40,000–50,000 years (Bowler et al. 2003) and ~62,000 years old (Thorne et al. 1999) and which include the oldest known cremation in the world. Skeletal material shows morphological variation and there is evidence of changing resource management as the ephemeral lake system, once a rich and wet environment became more arid (Hope 1981). As in other parts of the world, changing conditions during the Pleistocene influenced the rate of population growth, also likely to have varied across the Australian continent (O'Connell and Allen 2004). At the south of the Murray River in northwest Victoria, over almost a quarter of a century, substantial mapping, protection, and recording of important sites within the region specified have contributed to our overall understanding of the human occupation within Australia and furthered our understanding of the journey to Australia by the Australian Aboriginal people (Pardoe 2006). Within the region identified, there are Holocene sites and others within a few thousand years of the terminal Pleistocene.

DNA from living Aboriginal Australians from the Darling River country has contributed greatly to knowledge of genetic diversity in Australia (van Holst Pellekaan et al. 2010) complementing this already powerful background of a Pleistocene presence in the Darling River area from archaeology. Participant families from the Paakintji, Nyemba, and Mutthi-Mutthi language clusters contributed DNA samples that have been extensively studied for maternal ancestry (mitochondrial/mtDNA) and genome diversity (van Holst Pellekaan et al. 2010; McEvoy et al. 2010). The results provide genetic evidence of maternal ancestry that are strong signatures of the past likely to represent descent from early lineages in Australia who made their way into the region, further diversity being generated into branches of a regional "tree." Direct maternal lineages shown by mtDNA are called "haplotypes," and where they show shared characteristics demonstrating common ancestry further back in time, they are called "haplogroups," more clearly thought of as "superfamilies." In the region described in this entry, these haplogroups/superfamilies are called M42a, S1a, P4b, and some that are not easily defined without representation from a broader area. It is suggested that at least eleven maternal lineages from mt haplogroup P4b descend from founders in the Darling region, reflecting an ancient local presence and are distinct from other P haplogroups in northern Australia and New Guinea. Most of these lineages are from several Paakintji-related language groups, and one haplotype (14) is thought to have been from the Wangkumara language group, traditionally located considerably further to the northwest. Cautiously taking all dating methods into account, even a conservative estimate supports an ancestral presence for ~25,000–30,000 years. M42a is very strong and includes representatives from both Nyemba, Gurnu, and possibly western Wiradjiri peoples, and ancient S1a is part of a superfamily seen in southern Paakintji, Tasmania, central and northern Australia (van Holst Pellekaan et al. 2010; van Holst Pellekaan 2011). Anecdotally supported, there are likely to be members of this lineage in South Australia but participation has not yet occurred.

A more extensive study using some of the Darling River samples examined variation across the complete biparentally inherited genome (McEvoy et al. 2010). These data support a model of some connection with people of Papua New Guinea but are harder to interpret locally because of the complexities of biparental inheritance and post-colonization mixing with Europeans. The value of these data for future

disease-associated studies is yet to be appreciated fully because the data sets need to be explored in many ways along with phenotypic information and with other sample groups if they become available. In summary, the mtDNA studies from the Darling River region show how valuable they are for exploring the relationships between Aboriginal people and the dispersal of peoples within Australia, and if genetic data from other Australian regions, especially of near neighbors, were to become available, another contribution can be made to the story of the past.

Key Issues/Current Debates

- *One legacy of the past* is an entrenched perception for many Aboriginal Australians that western scientists are intent on showing a hierarchy of peoples where indigenous groups are at the bottom. The effort of many researchers over recent decades has been to show that this attitude of the past does not drive research today and is neither accurate nor useful, and yet the perception persists. Unhelpfully, the presentation of the Human Genome Diversity Project (HGDP) to indigenous Australians in 1997 perpetuated this perception and that of the notion that indigenous people are "vanishing" peoples. It is so well remembered today that the experience and publicity that it generated is frequently raised and has set back the efforts of many Australian scientists who have worked hard with Aboriginal organizations and individuals to present the benefits of genetic research, to involve participants in projects and to deal together with the negative concerns.
- *Uneven responses from Aboriginal and Torres Strait Islander peoples*. Aboriginal people have been involved with professional organizations such as the Australian Institute of Aboriginal and Torres Strait Islander Studies and the Australian Archaeological Association in the development of guidelines for ethical conduct in research for some decades (AAA 2004; AIATSIS 2011). In the case of genetic research, response is also uneven. The value of work already done is not disputed by the Aboriginal people involved or seeking inclusion, and there are a growing number of indigenous groups in Australia making use of DNA and attempting to use this data to better understand their ethos and how they are placed within a global context.

  > It is the view of my people that we are now in a golden age with technology and as such we enjoy, appreciate and employ people to carry out studies in consultation with us regarding our heritage. (Dugay-Grist, *pers.comm.*)

However, there is still resistance to genetic research by others, many of whom are reluctant to take the opportunity to engage in dialogue. If this resistance persists, the extra richness contributed to history by western science may never reach many of those to whom it is bequeathed by ancestors. Presently many Aboriginal societies of Australia are lacking knowledge of the views and studies of academia relating to their ethos.

- *Ancestry-focused genetic research* may be seen as a threat to traditional belief systems, and it must be acknowledged that for all peoples, contrasts between science and religion present challenges. In Australia, these conflicts began with the impositions that included the conversion to other religions during colonization. In practice, many Aboriginal Australians show an ability to accommodate their sense of creation by ancestral beings in the natural world, known as the Dreaming, scientific knowledge, and spiritual experiences into their belief system. Conflict of this nature has not arisen in many research projects where scientific evidence is used to reinforce and emphasize the ancient history of Aboriginal people in Australia.
- *Is ancestry-related genetics separate from genetics for health*? Not essentially, because although the focus of studies may be centered around specific questions, the data that are generated from DNA studies can be interrogated for separate questions. This issue has become more relevant as complete genome studies become available. Thus, the raw data

from a study such as that by McEvoy et al. (2010) confirms deep ancestral history and connection with other peoples from Papua New Guinea, but with further work, the results of the study should also be useful for exploring genetic variation in regions of the genome relevant to health and well-being. Aboriginal Australian people are not being *singled* out in genetics research but are being *left* out of medical epidemiological studies, and this may constitute another form of disadvantage. Until we understand the extent of genetic diversity in all populations, we will not know if there are specific variations in the genomes, resulting from a long period of adaptation to conditions and lifestyle that we need to understand for relevance to health. Since colonization, a different lifestyle was foisted on people, diet, and activity, and social circumstances changed dramatically. Both human settlers and introduced animals brought different pathogenic organisms, the adverse effects of which were influenced by social degradation and disadvantage. Fundamental understanding of genetic variation, ancestral and present, is a baseline step to working out details of cellular mechanisms, influenced by aspects of the social and physical environment that in turn influence wellness and illness.

- *Identity*, *rights*, *and connectedness*. For some, there is a fear that genetic research might produce results that *erode identity*, especially where colonization has imposed separation of families, mixed partnerships, and forced relocation. There is concern for some that native title claims might be threatened by genetic research (not part of the criteria for claimants). The inclusion of admixture estimates in published reports has raised comments from several critics, who again raise the issue of a potential return to classification of people based on blood quotient or genetic quotient estimates. A paucity of indigenous control or involvement in genetic projects that tend to be proposed by scientists from western style institutions is one reason why lack of accurate information tends to exacerbate these concerns. The long-term *custody* of samples, data, and confidential information in relation to DNA studies requires resolution.

Challenges for Western Scientists

- These include lack of experience and understanding of indigenous issues on the part of researchers trained strictly in science subjects that do not include social perspectives, and difficulty in explaining complexities of DNA, inheritance patterns, and technical and analytical methods. There is a need to report results in a culturally sensitive manner that does not compromise accuracy. Reporting may not give results that "suit" expectations. For example, skeletal DNA may be studied at the request of communities who are wondering if the remains can be shown to be closely related or ancestral remains. A potential conflict of interest can be avoided if the community/families understand what sort of outcome might be expected and realize that negative or "non-matches" do not necessarily exclude relationships that are generated nonbiologically, highlighting the need for clear explanation before projects are undertaken.
- Western scientists are also working in a research environment that requires success in funding submissions to cover costs of research and time frames that do not always allow for lengthy delays. Thus, Aboriginal people who become involved in research projects also have a responsibility to respond to requests and agreed tasks in a timely manner if research is supported. Lack of or negative response from indigenous organizations who act as "gatekeepers" does not always equate with wishes of participants and may result in loss of hard-earned funding.
- *Data sharing*. The secondary use of data that is generated from projects goes beyond the immediate published reports that emanate from discrete projects. The expectation within the scientific and academic communities that results be made available to other legitimate researchers has resulted in large databases that are accessible also to the public. There are strong arguments against this policy from many quarters and the issue is not resolved.

International Perspectives

Indigenous peoples in all continents, with familiar experiences of colonization by the now dominant "others," have been included in archaeological and genetic studies, enriching the story of human dispersal. Many of the issues that are raised by Aboriginal Australians have parallels elsewhere, and there are similarly uneven responses to research. Two contrasting cases from the north American continent were addressed by McInnes (2011) describing the positive experiences of one study that investigates cardiovascular conditions in a Canadian First Nations community who have played an active role in developing the research. Canadian guidelines for researchers are extensive and freely available as models for ethical conduct in any context, stressing respect, partnerships, and collaboration. Even with good intentions on the part of researchers, projects can founder as in the case of the Havasupai v. Arizona State University (McInnes 2011) where original consent was broad, apparently including the study of causes of "behavioral/medical" conditions, but it would seem that discussions with communities centered on diabetes research which became the part well understood. When other projects used the same samples, the community felt wronged, stigmatized, and offended. This unfortunate situation resulted in a well-intended research project foundering and the institution taken to court by the indigenous community.

Future Directions

- Researchers need to *understand the concerns of indigenous peoples*, acknowledge the hurts of the past, take time to study their culture, show respect for indigenous knowledge, and refrain from inappropriate language such as telling them that they will "vanish." We are all a product of mixed ancestry through different pathways. Indigenous Australians, like other indigenous populations, are deeply spiritual people who hold on to their creation stories and believe that much of their landscape is due to good and evil events of great import. DNA studies can easily fit into both the spiritual and everyday part of indigenous people's lives. Within most cultures, there is nothing that excludes such studies as long as it is done in consultation with those peoples and respect is shown for the wishes that may arise.
- Successful strategies are *preparedness to engage personally* with communities by close contact throughout planning and implementation of projects, where possible including indigenous personnel in the team. Building trusting relationships with clearly understood rights and responsibilities for both researchers and indigenous participants is essential. It is abundantly clear that, for consultation and negotiation to succeed, researchers need to demonstrate willingness and ability to meet with and engage Aboriginal people and organizations frequently, in their own place, on their own terms, and with appropriate explanatory documents. In turn, reciprocal respect from Aboriginal people should include honoring arranged consultations and responses to researchers in a timely manner.
- *Appropriate explanations* to outline the project, benefits, and risks are more successful if researchers enlist the assistance of indigenous people in the development of documents, diagrams, and dissemination of results. Information that states clearly the intention and possible outcomes of the research needs to be available in language suited to the needs of people with different education experiences, as well as conforming to the expectations and demands of the law and institutional and regional ethics committees. This may require sets of information at different levels of language that at the same time give the essential accurate information, and it may mean frequent repetition of verbal explanations. It is a long-term commitment, as ongoing progress reports to the communities and individual participants are necessary to maintain trust between parties.

Genetic heritage and belongingness: The history written in our genes tells us about immediate genealogies and also distant relationships that are far deeper than those defined by shared

cultures, language, or local community. Genetic diversity reflects a great time depth because it is not generated as quickly as language and cultural diversity, yet our sense of "belongingness" identifies with these more recently acquired attributes. It is not necessary to allow concerns about global origins obscure the value of exploring indigenous connections within Australia. Surely these are of interest to people, for whom remembered stories about connections with neighbors may be explored with DNA technology. Aboriginal Australians will be enriched if they locate more of the ancestral remains in institutions throughout the world and in the Australian landscape in conjunction with the relevant Aboriginal community to appreciate the value of the human evolutionary story that complements the connection to land.

The human colonisation of Australia stands as an ever unfolding global saga. It provides the virtual bookend to the world's greatest migration story, a story that illuminates the very nature of what it means to be human. In that context, for myself of latter-day European descent, it constantly poses that challenging question "Who am I" in this strange land. The answer to that question can only be sought by placing my own ancestral origins in the total context of that mega-migration event that changed the face of Australia some 50–60,000 years ago.

Indigenous Peoples, Working with and for

Shadreck Chirikure
Department of Archaeology, University of Cape Town, Cape Town, South Africa

Introduction

It is a universally acknowledged fact that archaeology has a very deep colonial heritage, especially in the former colonized regions of the world (Shepherd 2002; Watkins 2005; Atalay 2006; Smith and Jackson 2006; Schmidt 2009). Indeed, the roots of archaeology as a discipline can be traced to nineteenth-century Europe where the emerging middle classes got fascinated with their past (Trigger 1984). When the colonial project escalated from the nineteenth century resulting in the colonization of most of the world by European powers, European men and women got enchanted with the history and past of the colonized (Pwiti and Ndoro 1999). In the case of Africa, it was only a few colonial officials and peripatetic scholars who were involved with the study of the past. As with other regions such as North America and Australasia, this early development of archaeology had little to do with the interests of indigenous people. The information generated was often used to control and better govern the colonies as well as provide some entertainment and amusement for the colonizers (Chirikure and Pwiti 2008). Clearly, in colonial times, archaeology was hardly conducted for indigenous peoples.

A comparative study of the archaeology that was practiced during the colonial times, irrespective of geographical location in the world, exposes cadastral points that map well into Bruce Trigger's colonialist archaeology (Garlake 1973; Trigger 1984). The discipline was practiced by the colonizers and their dependants with little meaningful involvement of the local people, who were thought to be uninterested in their past. An archival study of early excavations carried out in different parts of Africa has

unearthed photographs which captured identical moments in the history of our discipline in colonial Africa. Most Africans were employed as laborers in the excavation of prominent sites such as Great Zimbabwe (Caton-Thompson 1931) and Mapungubwe (Fouche 1937) as well as some Swahili towns of east Africa. The same can be said of West and North Africa. The National Museums and Monuments of Rhodesia, a body tasked with the administration of archaeology, only employed blacks as assistants for most of the twentieth century. Black archaeologists only joined the organization at independence in 1980.

Local people were only valued for their labor and historical knowledge such that their names did not even feature in site reports (Shepherd 2002; Chirikure et al. 2010). For example, in his Great Zimbabwe excavation report, Robinson (1961) states that he was assisted by six Africans, of which the most intelligent was a Rozwi one. Because their names were not recorded, we do not know them, but the resulting publications have immortalized Robinson's name. To make matters worse, the same archaeologists were "knowledge parasites" for they depended on locals for interpretive leads. In fact, Caton-Thompson (1931) made it clear that it was impossible to interpret Great Zimbabwe as an outsider without understanding the African value system, but luckily for her, she got most of the inside information from the unsung heroes – her laborers. These indigenous people were not considered as consumers of the past, neither were they seen as knowledge producers – they were just mere assistants. This lack of meaningful involvement has created a fundamental problem that haunts archaeology to this day – that is, the failure to attract indigenous archaeologists. In fact, most post-colonial archaeologies are all meant to redress this (see Schmidt 2009). Atalay (2006) has identified the same problem in the United States where Native Americans seem to lack an interest in the subject.

Bureaucratic structures were also created to administer the protection of the past, its study, and display. Legislations were established that institutionalized archaeology as a discipline and also established museums as administrative centers. By 1969, South Africa had improved earlier antiquities legislations and promulgated the 1969 National Monuments Act, which also led to the establishment of the National Monuments Council. Other countries such as Rhodesia and Botswana also followed and established similar laws. The colonial legislation had no place for indigenous communities or their values. In fact, the laws criminalized the use of archaeological places by local communities (Chirikure and Pwiti 2008). Although the legislation in South Africa and Botswana has since been amended, colonial legislation is still in operation in Zimbabwe, where the only amendment was the name change from Rhodesia to Zimbabwe. There is no big difference between the new legislation and the old because the rights of local communities and indigenous groups are limited. Besides, the same bureaucratic infrastructure operates in independent countries, which is why recruiting indigenous people into archaeology in countries such as South Africa has been an uphill task (Schmidt 2009).

Colonialism destroyed the fabric of communities through the imposition of borders and boundaries. Land alienation also had the same effect which was not reversed at independence (Pwiti and Ndoro 1999). This resulted in different indigenous groups being exposed to the heritage of other groups which they had no relationship with. Because it was not their past, they simply ignored or disrespected the archaeology of others. Post-independent Zimbabwe saw an upsurge in black archaeologists who are now employed in most countries in southern Africa. Botswana and Kenya have also witnessed this development just as Nigeria and Senegal in West Africa. The archaeology is still practiced along the colonial lines; what is changing is the color of archaeologists. As such, there is a need for massive programs in decolonizing African archaeology, its methodologies, and its outputs (Schmidt 2009). Lane (2011) has lobbied for the production of multiple archaeologies to make sure that all voices, both dominant and dominated are heard. Given the dominance of the academy which appropriates heritage for its own purposes, there

is need for a seismic shift towards practicing an archaeology that is for, with, and by the local people (Atalay 2006). That way, archaeologists will be working with and for indigenous peoples. This contribution seeks to discuss the concept of working with and for indigenous peoples from an African perspective. It also outlines some of the inherent structural challenges and suggests some paths to be navigated as the present unfolds into the future.

Definition

Who Are Indigenous Peoples? Are They Identical Across the Whole World?

A question that elicits different responses from archaeologists in the different continents is what is indigenous archaeology? According to Watkins (2005), indigenous archaeology is that which is done by, with, and for indigenous people. This definition makes strong sense if the colonial ancestry of archaeology is considered. Archaeology had no place for indigenous peoples who despite providing knowledge that was used to interpret the past were often challenged for being unscientific. Thus indigenous archaeology is a form of archaeology premeditated to restitute and empower the indigenous people to control their own destiny (Schmidt 2009). Indigenous archaeology seeks to tilt the balance of power in world archaeology in the direction of the previously colonized and marginalized peoples. It seeks to achieve this through doing archaeology by, for, and with indigenous people. The most important issue in indigenous or postcolonial archaeology is the definition of the concept of indigenous.

Watkins (2005) presents a number of definitions on what does it means to be indigenous. He draws from the International Labour Organization definition which states that people may be "regarded as indigenous on account of their descent from the populations which inhabited the country, or a geographical region to which the country belongs, at the time of conquest or colonization or the establishment of present State boundaries and who, irrespective of their legal status, retain some or all of their own social, economic, cultural, and political institutions". There are four general distinguishing factors for indigenous people: descent from the "first comers" on the land, lack of economic and political power, cultural uniqueness or non-domination, and some form of group identity (Watkins 2005). The issue of indigenous has political connotations for it implies marginalization, disempowerment, and lack of independence. In many ways, indigenous peoples are treated as second-class citizens on account of their ancestry and political and economic inferiority.

A global identification exercise would list the Sami of Northern Europe, the so-called First Nations of Canada, Native Americans, Aborigines of Australia, the Maori of New Zealand, the San and Khoisan of southern Africa, the Pygmies of Central Africa, and Hadza and Dorobo of East Africa as the quintessential indigenous peoples. This identification of who is indigenous is very problematic for sub-Saharan Africa. In regions such as southern Africa, the precolonial populations consisted of black agriculturalists who occupied the summer rainfall areas. These practiced sedentism, cultivated seasonal crops, worked metals, and made pottery. Then, there are also the so-called hunter-gatherers who were mobile, non-sedentary, and subsisted on hunting and gathering. In the Cape region of South Africa and Namibia, there are also the Khoisan and Damara-Nama peoples who were pastoralists. The archaeologist Huffman (2007) clearly makes the point that this division of African groups prevailed at the time of contact and has deep roots. For example, the black agriculturalists are believed to have migrated from North West Africa, populating southern Africa by the first millennium CE. This means that when colonialism began, these groups were on the landscape for close to a 2000 years. They had complex relationships with hunter-gatherers, lived with them, and traded with them (Schmidt 2009). Among many sites, the Iron Age settlement of Bosutswe in Botswana seem to have been occupied by both farmers and hunter-gatherers. If we revisit the criteria used to identify who is indigenous, we realize that because Europeans found hunters

and gatherers on the landscape at contact, they also thought that they were marginalized and culturally pristine. This way of thinking is ethnocentric and was shown to be untrue by Wilmsen (1989), Hall and Smith (2000), and Manyanga (2007) who encountered archaeological sites that have hunter-gatherer and farmer material culture. It therefore means that any definitions of indigenous that privileges the so-called minorities and ignores the farming majority are missing the point. In fact, how can people who have lived in an area for 2000 years or more not be regarded as indigenous? By failing to view all Africans both farmers and hunter-gatherers, as indigenous we will be imposing a western worldview which dichotomizes nature (bushman) and (culture) farmers. In any case, in a region such as southern Africa, the division between hunter-gatherers and farmers has disappeared in the last century such that if indigenous archaeology is to be successful, it has to consider all the nonwhite people as indigenous. This is the premise adopted by a collection of essays in Schmidt (2009).

Controversial as this may sound, there are very few black archaeologists in countries such as South Africa, and to push for an archaeology that favors only the Khoisan and San descendants would turn the already dire situation into a crisis of cataclysmic proportions. Thus, if indigenous archaeology is to develop in Africa, the definition of indigenous must be broadened up and the rest of the world must see the situation from the complexities of Africa and not from the lenses of their own areas.

The people of sub-Saharan Africa have all been marginalized in the production of the past such that including all sections of the previously disadvantaged will decolonize the discipline and take it forward. In any case, the concepts of indigenous archaeology in places such as Australia do not look at which Aboriginal group was dominant in precontact times; Aborigines are Aborigines. While groups such as the San should not be neglected wherever they still exist; attention should not only be solely focused on them. Such a broad-based approach will create a conducive climate for the successful takeoff of indigenous archaeology in Africa.

Historical Background

Working with and for Indigenous People

Although there is a union of thought between the different practitioners of indigenous archaeology with regard to the need to meaningfully bring the marginalized into the center of archaeology knowledge production and dissemination, a number of approaches have been developed to realize this end (Chirikure and Pwiti 2008). The approaches differ from country to country and continent to continent. The most common method of working with indigenous people is that of collaborations in archaeological research and heritage protection. This working together is often precipitated by legal requirement which make it mandatory for researchers to demonstrate a strong local community component in their research teams. This will also produce in some cases the joint ownership of results. According to Nicholas (2001: 163), in British Columbia, "consultation with the appropriate First Nation is now a prerequisite for obtaining an archaeological permit. This requirement occurred in response to demands for greater Aboriginal representation, and overall, has had a positive impact on the discipline as it makes archaeologists more responsive to contemporary needs and their work more relevant." The Secwepemc Ethnobotany Project that ran between 1991 and 1998 in Canada also had representatives of indigenous people in the design of the project and gave them some ownership of the results. In Australia, Smith and Jackson (2006) also meaningfully collaborated and worked with the Barunga-Wugularr communities of the Northern Territory and the Ngadjuri people of Burra, South Australia. This working together involves joint project design and control over the results of the research. Nicholas (2001) also discusses the importance of workshops between indigenous communities and academics which bring the worldview of the local people into consideration. All these are successful cases of working with and for indigenous people.

Indigenous worldview – the set of beliefs, values, knowledge, and behavior by which people make sense of the world around them – is critical in knowledge production. Such a worldview is a

necessary guide not just for interpretation but also for managing the heritage. The Clanwilliam Living Landscape Project directed by John Parkington of the University of Cape Town in South Africa uses indigenous people to interpret sites as well as to earn a living through their traditional crafts. Although Parkington acts mainly as the fund-raiser, indigenous people run the project and gain immensely from economic opportunities created through interpreting and protecting their past. This is a strong example of working for the indigenous peoples because they control knowledge production and benefit socially and economically from it.

In Mozambique, archaeologists conscious of the lack of involvement of indigenous peoples in the protection of sites have worked with spiritual and traditional leaders to protect the sites. Jopela (2011) discusses the use of spirit mediums in protecting the rock art sites of Chinyamapere in Mozambique. The spirit medium organizes people and controls access and thus hold custodial rights on behalf of the community. Archaeologists are also working as advisers to local communities. The archaeologist Peter Schmidt of the University of Florida, Gainesville, is advising indigenous people in areas that he carried out research in Tanzania to develop archaeological tourism in the country. The archaeotourism project is directed by the indigenous people, and they consult Schmidt when the need arises. After working with indigenous people, he is now working for them.

Training and publications are two of the areas that are crucial in developing indigenous archaeology and indigenous peoples. Nicholas discusses a robust training program of indigenous people in Canada. Many First Nation peoples are getting graduate degrees which place them at the nexus of knowledge production. There are also publications which are designed to give voice to indigenous peoples. There is the *American Indian Quarterly* which publishes important studies on indigenous archaeology and related subjects. The journal *Archaeologies* which is owned by the World Archaeological Congress also publishes works which support indigenous views of the past. However, such outlets are very few in Africa which deprives indigenous archaeologists of opportunities to disseminate their archaeological results which may not necessarily be, in tandem with established positions (Schmidt 2009).

The use of language which respects and does not denigrate indigenous people is one way of working for indigenous communities. For example, while other researchers do not give the names of their informants, Schmidt has always provided the names of Tanzanian master smelters and has respected the knowledge contained in their oral traditions. This respect for local people and local knowledge is very important in empowering indigenous communities. Thus, working with and for the indigenous people requires well-meaning endeavors in decolonizing the practice of the subject, thereby making sure that local people meaningfully participate, benefit, and play a meaningful role in protecting their past.

Key Issues/Current Debates

Regardless of how colonialism developed in the different parts of the world, the common denominator is the fact that archaeology developed as a western curiosity with no meaningful involvement of the local communities. Furthermore, archaeology developed very closely with the colonial states, often creating information which was used to suppress and dominate local populations. Not surprisingly, in many postcolonial contexts, it is important to redress the omissions of the colonial period through collaborating and working with local communities. This collaboration must be meaningful and not half hearted. Extremists may argue that even in colonial times, archaeologists in regions such as east and southern Africa and North America were using oral traditions and ethnographies to understand the past (see McGhee 2008). Schmidt's well-known study of iron working in Tanzania is just but one of the many examples (see Schmidt 2009). Similarly, Huffman's work (2007) combines Shona history, anthropology, philosophy with Portuguese documents, and Venda anthropology to understand the spatial organization of the elite Zimbabwe settlements. Schmidt (2009) has realized that although he was

using oral traditions to incorporate indigenous perspectives into the study of the past, more was needed in the form of collaboration. This is no wonder why he is helping communities to chart their own destiny as far as the study and use of the past is concerned. This is a very beneficial way of working with and for the communities.

Then, there are some who still view archaeology as a science which produces general laws for predicting human behavior. Such works, although they draw from oral histories, ethnographies, and the so forth, challenge the same sources for being unscientific. Obviously, there are so many colonial overtones to this kind of approach which unfortunately still dominate southern African archaeology. Lane (2011) has criticized such approaches for perpetuating images of a timeless and unchanging Africa under the guise of science. Ironically, if indigenous people write their own perspectives, they are criticized heavily and rebutted, but it is fine for the dominant approaches to use interviews from such people. This means that indigenous people cannot write about their past, but they must provide information to the dominant to write it for them. This is one reason why it is very difficult to develop an indigenous archaeology in southern Africa. This is a fundamental point missed by McGhee (2008) in his critique of indigenous archaeology. To say that indigenous people must be meaningfully involved in knowledge production and dissemination is not to say that nonindigenous peoples must not write about the past of indigenous people. There is a fundamental flaw in the status quo where there are very few indigenous archaeologists. What proponents of indigenous archaeology are saying is that we must make sure that we involve indigenous people and train them in the study and writing of the past in order to bring their perspectives to the fore. This is tantamount to decolonization of the discipline.

There is nothing new in this argument; in contexts such as mining, companies are now creating partnerships with host communities and indigenous groups to develop and empower those communities. Gone are the days when areas around mines remain underdeveloped while their resources are enriching other regions. As such, it is important to make sure that those who work with communities transfer some benefits. Of course, the resources that archaeology has are not comparable to those of mining houses, but it is important for us to do our part with the little that we have.

For working with and for indigenous people to be fully established as a way of studying the past, there is need to train a number of indigenous archaeologists. This can promote a decolonization of the discipline. Countries such as Zimbabwe, Tanzania, Nigeria, and Kenya have trained indigenous archaeologists who are giving different perspectives on the past. The only problem, however, is that they are part of the academy; they publish in international journals which may not publish results that are thought to be radical. There have been recent cases of situations where big international journals have made defendants of established positions referees of papers that are revisionist in nature and motivated by indigenous experiences. Because the indigenous perspectives challenge the dominant position, often they are not published because experts do not like them. This means that indigenous peoples cannot establish research agendas; they are conditioned by the thoughts of the experts. Although, there are some journals which welcome different viewpoints and are a source of hope, this scientific autocracy is perhaps one single most important factor that stunts the growth of indigenous perspectives in southern Africa.

International Perspectives

The definition of who is indigenous and who is not is very crucial because in sub-Saharan Africa, the way indigenous is defined has potential to include and exclude some local groups of people. This is where local contexts and histories are crucial in understanding the cultural development of a region. In regions such as southern, eastern, and central Africa where there are minorities such as the San, the Pigmies, and the Hadza, adopting a narrow definition will make these people the only indigenous ones. And yet, there are other groups particularly those practicing a pastoral or mixed

agricultural way of life who also have a deep history in these areas. The Bantu people have been resident in sub-Saharan Africa for a very long time. There are also indications that often if people had lost their animals, they could become hunter-gatherers. All this indicates the fluid nature of the division between who is indigenous and who is not. As such, for indigenous archaeology to take place in Africa, it must be applied to all black people that way people can identify with it. This is no wonder why Watkins (2005) failed to find many examples of indigenous archaeology in Africa. The most important point therefore is that the definition of indigenous differs from context to context and continent to continent. In Africa, virtually all black people were colonized and suffered the excesses of colonialism. These people were all excluded in the production of their past. It is important to have them on board in the researching of the past.

There are some researchers who may feel that archaeology is a science and the production of the past must follow scientific principles (Huffman 2007). Therefore, methodologically, if local communities cannot fit into a researcher's methodology, then they must be excluded. Research is all about making predictions and validating them with data. An extension of this view argues that indigenous archaeology privileges one group of people at the expense of others in the study of the past (McGhee 2008). These standpoints miss the point that indigenous archaeology is restitutional in letter and spirit. It seeks to empower groups of people who were historically marginalized from the production and consumption of their past. This is an ethical standpoint which aims to bring more people into the study and communication of the past. There are very few black archaeologists in sub-Saharan Africa who are writing the past from their own point of view. The majority lack access to high-profile publications which silences their thoughts. It is not that they agree with narratives that were written by colonialists to their ancestors' total exclusion; often, their ideas are challenged for being unscientific. If archaeology is to transform so that it can be sensitive to the needs of local people, archaeologists must work with and for local people. As such, one can practice scientific archaeology but still work with and for local people. What is ethically inappropriate is that as researchers we profit in terms of career development but without involving any of the communities we work for. Colonialism in Africa lasted for many years, and it will take a longer time to reverse some of its excesses. Indigenous archaeology is one of those ways in which local people can be empowered to master their own destiny. That way, we will be able to incorporate different versions of the past rather than those informed by what we think is important as scientists.

Future Directions

One of the major goals of postcolonial archaeology is to transform archaeology from an elitist, almost colonial discipline into a decolonized practice where multiple perspectives flourish. One way of achieving this is to work with and for indigenous peoples. Working with and for indigenous people is not a one-way traffic; it needs the commitment of the indigenous people, the archaeologists, and all stakeholders. Collaboration in research projects and control of access are some of the ways used to ensure that archaeologists work for and with indigenous people. This has created some good results in Canada, Tanzania, South Africa, and Australia. The only challenge appears in issues such as copyright and publications. Is it possible for a researcher working in a community to coauthor the resulting publications with all the members? Is coauthorship an issue or what matters is whether the author has deposited the material in communities? Some archaeologists distribute their books in the communities which they work and this helps, but there would be need for more information storage. Given that archaeology is often seen as a luxury, who will build local storage facilities? Publications are also an important issue, indigenous people do not have control, and as such, multiple perspectives may be ruthlessly strangled in cases where researchers seek dominance at the expense of studying the past. Despite the challenges, the outlook for postcolonial archaeology and its emphasis on working with and for indigenous communities is bright.

Indonesia's World Heritage

Noel B. Salazar
Cultural Mobilities Research (CuMoRe), University of Leuven, Leuven, Belgium

Introduction

The Republic of Indonesia counts around 17,000 islands and a rich cultural heritage that bears clear traces from a long history of trade and exchange across the archipelago and with the wider Indian Ocean region. Until 2012, the country's cultural World Heritage sites – Borobudur Temple Compounds (1991), Prambanan Temple Compounds

(1991), and Sangiran Early Man Site (1996) – were all located in Central Java. Another 19 sites, more spread across the main islands, are on UNESCO's Tentative List.

Historical Background

Most of Indonesia's cultural World Heritage sites so far are located in the central part of Java, the fifth largest and most populated island of the archipelago (including the capital, Jakarta). Only in 2012, the "Cultural Landscape of Bali Province: the Subak System as a Manifestation of the Tri Hita Karana Philosophy" was added to the list. The earliest signs of habitation in this fertile volcanic area are prehistoric. In the 1930s, the German paleoanthropologist Gustav von Koenigswald started a systematic geological survey of Java. At Sangiran, nearby the city of Solo (Surakarta), this led to the discovery of over 50 fossils of *Meganthropus paleo* and *Pithecanthropus erectus* ("Java man," now reclassified as part of the species *Homo erectus*). The outstanding hominid fossils and artifacts found nicely illustrate the development of *Homo sapiens sapiens* from the Lower Pleistocene to the present. For this reason alone, Sangiran has become one of the world's key sites for the understanding of human evolution.

From the seventh century CE, Central Java was dominated by Hindu and Buddhist kingdoms (Salazar 2016). This led, in the mid-eighth century, to the construction of Borobudur, the lower terraces of which have the typical trademarks of Javanese Hindu architecture. While the basic plan was kept, during the construction phase builders changed it from either a prehistoric Indonesian or Hindu monument into a Buddhist shrine, with 2,672 relief panels, 504 Buddha statues, and a central dome on top. Seen from the air, the structure looks like a giant Buddhist mandala. Close to Borobudur, near the village of Prambanan, a large group of Hindu temples was erected. The complex, one of the largest in Southeast Asia, was consecrated in the mid-ninth century, after a construction period of around 25 years. One century later, the Hindu court and most of the population moved to East Java, and the 224 temples were left behind. The structures themselves collapsed during an earthquake in the sixteenth century. Borobudur was abandoned around the same time, too, probably after a series of eruptions from nearby Mt. Merapi, and lay buried for centuries under layers of volcanic ashes.

Islam, coming mainly via India, gained ground in the inner areas of Java during the sixteenth century. The Dutch began to colonize the archipelago in the early seventeenth century. Cornelis A. Lons, an officer of the Dutch East India Company who made an excursion to Prambanan in 1733, reported about the damaged statues he found among the piles of stone blocks. During the brief British presence on the island under Sir Thomas Stamford Raffles (1811–1816), a full survey of the ruins was commissioned. Raffles, who had a personal interest in Javanese antiquities, also ordered the excavation of Borobudur. The work was started by the Dutch engineer Hermann Cornelius and continued for many decades by the Dutch East Indies government. The public appreciation of Borobudur and Prambanan, however, developed rather slowly. For a long time, colonial residents carried off sculptures for garden ornaments or "souvenirs," while local villagers used foundation stones for construction material, and "trophy hunters" and thieves tried to make a profit out of what they could take away from the monuments.

Indonesia's legal framework for cultural heritage preservation and management goes back to the colonial period (Kagami 1997). In 1901, the Committee for Archaeological Research on Java and Madura was set up by the then Dutch East Indies government. In 1931, an ordinance on monuments (Monumenten Ordonnantie S. No. 238: 1931) was established, with the aim of preserving historical monuments (mainly within the colonial domain). Even though the intentions were different, these policies were taken over by the Indonesian government after independence in 1949. While the colonial government had adopted such policies to demonstrate and justify its presence as the preserver of Indonesian cultural heritage, the Indonesian government does it mainly to assert its sole sovereignty over its "national

patrimony." Indonesia signed the 1972 UNESCO World Heritage Convention in 1989. Shortly afterward (in 1992), a new law concerning items of cultural property was enacted to replace the former ordinance (Ministry of Culture and Tourism 2003).

Key Issues/Current Debates

UNESCO Involvement

Barely 2 years after independence (in 1951), a UNESCO Office was established in Jakarta. Although serving the wider Southeast Asia region, the office helped in bringing Indonesia's magnificent cultural heritage under global attention. In 1972, UNESCO launched a 25-million USD safeguarding campaign to restore Borobudur (the second action of its kind after the 1960s operation in Egypt to relocate Abu Simbel). Concurrent with the elevation of Borobudur and Prambanan to World Heritage sites in 1991, UNESCO collaborated with UNDP and the former Indonesian Directorate General of Tourism in the ambitious Cultural Tourism Development Central Java-Yogyakarta Project (1991–1994). The intergovernmental organization was also involved in the rehabilitation of the structurally damaged Prambanan Temple complex after the 2006 earthquake and the more recent cleaning up of volcanic ashes at Borobudur caused by multiple eruptions of nearby Mt. Merapi.

UNESCO's involvement has not always been perceived positively at the local level, mainly because people feel left out in the conservation of the sites, leading to conflicts as "classical"/high culture is preserved over vernacular/low culture (Wall and Black 2004). At Prambanan, for example, there is an ongoing conflict with the local community regarding the name of the complex. While it was inscribed on the World Heritage list as "Prambanan Temple Compounds" (No. 642), the people of Prambanan village have always referred to it as *Candi Rara* (or *Loro*) *Jonggrang* (Javanese for "temple of the slender maiden"). This refers to a popular legend relating that the statue in the north chamber of the central Shiva shrine does not represent the Hindu goddess Durga but the Javanese princess Loro Jonggrang. The tensions recently intensified when, in accordance with Article 268 of UNESCO's Operational Guidelines for the Implementation of the World Heritage Convention (UNESCO 2008: 69), the text "Candi Rara Jonggrang" on a newly placed signboard was replaced by "Candi Prambanan." Through initiatives such as the 2008 Prambanan Camp for World Heritage Volunteers, which enabled to increase the heritage awareness of local youth, the negative perception of UNESCO was somewhat adjusted.

Tourism

Tourism is not much of an issue at the archaeological site of Sangiran (and its nomination as World Heritage has not brought any substantial change in that respect). At Borobudur (the single most visited tourism attraction in Indonesia) and Prambanan, in contrast, the challenges related to tourism are ongoing. Much has to do with the ways in which both sites are managed. The park surrounding the monuments and the related infrastructure (ticket booths, interpretative services, and parking lots) is administered by PT Taman Wisata, a state-owned enterprise. Souvenir stands, food stalls, and other tourism-related structures outside the main grounds fall under the control of the Provincial Tourism Office of the province in which they are located (Borobudur is in Central Java, while Prambanan is in Yogyakarta). The actual monuments, however, resort under the responsibility of the National Archaeology Department of Indonesia (and, with the ongoing process of regional autonomy, increasingly the provincial archaeology departments). Not surprisingly, this fragmented distribution of authority leads to multiple problems, including the development of ill-planned tourism infrastructure (Salazar 2010a). As there is no limit on visitor numbers, vandalism is a serious issue at both Prambanan and Borobudur. There is little if any on-site interpretation available, and the general disrespect for the sites is a major problem among domestic tourists, who comprise around 80% of all visitors. In addition, local tour guides have a hard time handling the increasingly diverse group of international tourists (Salazar 2008, 2010b). Tourism development at both sites has been

severely criticized for not including the local community (Hampton 2005).

Environment

Indonesia's cultural World Heritage sites are located in an environmentally fragile area, known as the Pacific Ring of Fire, where a large number of volcanic eruptions and earthquakes occur. In fact, Mount Merapi (25 km from Prambanan and 28 km from Borobudur) is one of the most active volcanoes in the world. In 2010, Borobudur was heavily affected by a 2.5-cm layer of acidic volcanic ash falling on the complex. In addition to the numerous earthquakes, causing stones to fall down and arches to crumble, the soft soil and heavy rains have led to the destabilization of the structure. The main complex at Prambanan was badly damaged during the 2006 earthquake, with large pieces of debris, including carvings, scattered over the ground and the structural damage being more extensive than originally thought. Only in 2010, the main temples were reopened to the public.

Economy

Indonesia's World Heritage generates both benefits and costs (Hampton 2005). Over time, there have been remarkable shifts in the (economic) value attached to the country's patrimony (Salazar 2011). In preparation for Prambanan to become recognized as World Heritage, the Indonesian authorities removed the market that had sprung up near the temple and transformed the surrounding hamlet and rice paddies into an archaeological park. Villagers, however, benefit economically from the souvenir stalls at the entry of the park, by their work inside the complex (as guides, watchmen, cleaning personnel, etc.) and by participating in the Ramayana Ballet, which is performed every night at the open-air and indoor stages on the west side of the complex. Borobudur has a similar history of challenges and opportunities. In 2003, for instance, the local community heavily protested against a provincial government plan to build a three-story art mall, known as "Java World," next to the protected monument because this would take away even more from their scarce benefits. The values of tourism for economic development, preservation of a cultural icon, and social justice for hundreds of poor hawkers brutally clashed in the controversy over Java World (Silver 2007). At both Prambanan and Borobudur, there is a continuous problem with vendors harassing visitors inside the park to buy their trinkets. Unregulated, predatory commercialization forms a serious threat to the cultural assets of the sites.

Religion

Indonesia is the country with the largest Muslim population in the world. Islam stands as a religion quite different from the religions of the Javanese people during the pre-Islamic period. The fact that Prambanan and Borobudur are located in what is now a predominantly Muslim area adds to the complexity of managing, maintaining, and interpreting the temple compounds. In 1985, Muslim fundamentalists who viewed Borobudur as a symbol of Indonesia's pre-Islamic pagan past bombed nine stupas on the upper terrace. The militants perceived the government's renovations of the site (largely for purposes of tourism) as emblematic of the state's refusal to embrace Islamic law. They therefore selected Borobudur as a target, and, in response, the government made it clear that all temples on Java were to be considered as heritage monuments, not religious or sacred sites where ritual activities are held (or, according to the ICOMOS description, as "religious complexes"). Recent Islamic terrorism attacks have mainly targeted tourism infrastructure (e.g., the Bali bombings), not heritage sites.

In order to accommodate the religious needs of the many Muslims working at and visiting the sites, a *musholla* (small building where Muslims perform their religious duties) was built right next to the entry gates. It is odd that, while visiting either Prambanan or Borobudur around prayer time, one can hear the Islamic call to prayer far into the compound. In contrast, the restoration of Borobudur and Prambanan has led to a revival of both sites as places of worship and pilgrimage for Buddhists and Hindus, respectively. Indonesia's official state policy (known as *Pancasila*) remains one that promotes religious freedom. Ironically, the ongoing process of democratization, started

after the fall of Suharto in 1998, has facilitated the spread of Muslim fundamentalism and increased the calls to have Muslim heritage such as the Great Mosque of Demak (since 1995 on the tentative list) included on the World Heritage list. It remains to be seen which influence religious fundamentalism will have on the archaeological excavation site and museum of Sangiran.

Politics

It is no coincidence that most of Indonesia's cultural World Heritage sites are situated on Java. After all, it is the central government in Jakarta that proposes candidates to UNESCO. During Major General Suharto's New Order era (1966–1998), the government (led by Javanese) strongly favored Central Java in their (re)invention of Indonesia, promoting it as the cultural heart of the nation (Dahles 2001). This serves as a reminder that, ultimately, a World Heritage site is the product of agency at the national level. Besides, the Indonesian government has its own heritage politics and national list of heritage conservation. The politics of heritage and the tensions between local, national, and international stakeholders have been at play across the archipelago. The case of the Tana Toraja settlements in the highlands of Sulawesi, on UNESCO's Tentative List, painfully illustrates that cultural heritage sites are often not the newly threatened landscapes of tradition they are imagined to be (Adams 2003). An even more problematic example is that of Pura Besakih, Bali's most celebrated temple complex, which underwent three failed attempts (mainly due to strong local protests) to establish it as World Heritage (Hitchcock and Darma Putra 2005). More generally, the democratic reforms and the shifting of power from the central government to the local level during the last decade have fueled an intense new "localism" that has had direct (and often negative) implications on cultural preservation (Silver 2007).

Future Directions

The Indonesian government has successfully managed to use the most iconic historical monuments within the country for tourism development while at the same time trying to intervene in their management in the name of their preservation as part of the nation's patrimony. These processes do not take a single course, but, rather, proceed in parallel, mutually influencing each other. Short-term gains in both must be assessed against long-term consequences. The promotion of the development of national culture has been one of the most crucial tasks of the Indonesian government since independence, as is clearly stated in Article 32 of the Constitution: "the Government shall develop the National Culture of Indonesia." However, the ongoing process of political decentralization (started in 2001) is adding to the number of political stakeholders involved and, consequently, making the management of World Heritage sites even more complex than it was before (Salazar 2010a).

With a view to enhancing the capacity of the Indonesian national and local authorities to improve the state of conservation (management) at Borobudur, the World Heritage Centre has developed a technical cooperation project under the Netherlands Funds-in-Trust with UNESCO. As long as such initiatives leave out the local communities as active stakeholders, they are doomed to fail. A reason for the lack of enough safeguards to protect the cultural values of sites is to be found in an underdeveloped understanding and therefore lack of appreciation of the value of these cultural resources by both the local community and the tourist alike. The UNESCO "Community Empowerment Through Heritage Education" program at Indonesia's three World Heritage sites is a good step in dealing with this issue. Finally, increased attention will be needed to address the fact that Indonesian World Heritage sites, despite their proclaimed universal value, have different meanings for different groups of visitors (Salazar 2008).

Indo-Pacific Prehistory Association (IPPA)

Ian Lilley
Aboriginal and Torres Strait Islander Studies Unit, University of Queensland, Brisbane, QLD, Australia

Basic Information

The Indo-Pacific Prehistory Association (IPPA) was founded in 1976 at a meeting of Indo-Pacific scholars held during the 9th Congress of the *Union International des Sciences Préhistoriques et Protohistoriques* (UISPP) in Nice, southern France. The association, however, has much earlier antecedents and traces its origins back to a meeting organized in 1929 by P.V. van Stein Callenfels during the Fourth Congress of the Pacific Science Association in Batavia (now Jakarta). Its immediate antecedent was founded, as the Far-Eastern Prehistory Association (FEPA), at a meeting in Manila in 1953.

Major Impact

With the creation of the current Indo-Pacific Prehistory Association in 1976, a number of goals were outlined:

1. To promote cooperation in the study of the prehistory and related subjects of eastern Asia and the Pacific and prehistorically related areas.

2. To help maintain direct communication among scholars working in the field of east Asian and Pacific prehistory through periodic congresses, regional meetings, colloquia, symposia, and the publication of the IPPA Bulletin. East Asia here includes Pakistan and north from there roughly along the line of 70° longitude and to the east.
3. To uphold and improve legal and scientific methods of prehistorical and related research in the field and in the laboratory and to help the countries in the IPPA area prevent illegal excavation and illegal trade in antiquities.

During the 35 years that have passed since that momentous gathering in Nice, IPPA has addressed itself without pause to the production of its annual Bulletin and its congresses (Pune, India, 1978; Dunedin, New Zealand, 1983; Peñablanca, Philippines, 1985; Tokyo and Guam 1987; Yogyakarta, Indonesia, 1990; Chiang Mai, Thailand, 1994; Melaka, Malaysia, 1998; Taipei, Taiwan, 2002; Manila, Philippines, 2006; Hanoi, Vietnam, 2009). The next conference will be at Angkor in Cambodia in 2014. Delegate enrolment at the most recent congress, in Hanoi, was over 600.

However, the second part of our third goal, that of preventing illegal activities, has never been developed until now, partly because the voluntary staff of IPPA have never had time or resources to invest in a problem that now threatens the survival, in some parts of the world, of any meaningful archaeological record at all. It is intended that this will become a significant role for IPPA in the future, as part of a move for IPPA to engage with the cultural heritage management sector.

Structure and Funding

The constitution of the association specifies a president, a secretary-general, and an executive committee of eight members. The latter must contain at least one member from each of the four general areas covered by IPPA: Northeast Asia (the former USSR territories east of 70° longitude, with Korea, Japan, and China), Southeast Asia (including Madagascar), South Asia (India, Pakistan, Sri Lanka, Bangladesh, Nepal, and Bhutan), and Oceania (Australia, New Zealand, and the Pacific Islands).

In 2010, Ian Lilley was appointed secretary-general to replace Peter Bellwood, who had held the position (originally as secretary and editor) since the Pune conference of IPPA in 1978. A new committee of eight has been elected (2010), and the editorship of the IPPA Bulletin is now in the hands of Peter Lape and Ben Marwick at the University of Washington in Seattle. IPPA has played a major role in the past in bringing students and younger archaeologists from the IPPA countries to its conferences, and in helping these scholars publish their research in the IPPA Bulletin for an international audience. In future, the publication effort will be integral to IPPA's stronger role in regional cultural heritage management.

IPPA is funded only by membership fees and IPPA Bulletin sales and has never had major institutional financial support. The Australian National University has assisted in the past through the provision of an association web site, a URL for the IPPA Bulletin (which is now being moved to Seattle), an email address, and a taxation-exempt university account to hold membership and conference income. A number of international foundations such as Ford, Wenner-Gren, Chiang Ching-kuo, and the Asian Cultural Council have helped to fund attendance at conferences by scholars from developing countries in the past.

Conclusion

IPPA has had no cultural heritage function until now, but future plans will see the organization support initiatives in cultural heritage management throughout its area of responsibility, beginning with a focused workshop at the 2014 Congress in Cambodia.

Inductively Coupled Plasma-Mass Spectrometry (ICP-MS): Applications in Archaeology

Laure Dussubieux
Elemental Analysis Facility, Department of Anthropology, The Field Museum of Natural History, Chicago, IL, USA

Introduction

Inductively coupled plasma-mass spectrometry (ICP-MS) is a multi-elemental analytical method with very good sensitivity. It is able to determine the concentrations of almost all the elements in the periodic table except hydrogen, carbon, nitrogen, oxygen, some of the halogen elements, and a few others. Limits of detection are below the ppb level for sample solutions and in the range of ppm or below depending on the element when connected to a laser ablation (LA) system for the direct analysis of solid samples. ICP-MS with introduction of acid digested samples can be considered as a bulk analytical method, while LA-ICP-MS is punctual and capable of targeting a very specific region on the surface of an object. The microsampling performed with a laser ablation system leaves no visible trace at the surface of the artifact, making LA-ICP-MS virtually nondestructive. ICP-MS with sample solution or LA has opened up new avenues of research in archaeology based on trace element fingerprinting.

Key Issues

Description of the Instrumentation

An ICP-MS is comprised of two main parts: (1) the inductively coupled plasma, which decomposes, atomizes, and ionizes the material to be analyzed in a very hot environment (temperatures can reach 10,000 K) that is sustained with a radiofrequency electric current produced by an induction coil wrapped around a series of concentric quartz tubes called the plasma torch; (2) the mass spectrometer, which filters the ions according to their charge-on-mass-ratio. For elemental analysis in archaeology, three types of mass spectrometers are typically used. Quadrupole and magnetic sector mass spectrometers are, by far, the most widely spread even if a few archaeometry laboratories are now equipped with time of flight (TOF) mass spectrometers.

Quadrupoles are composed of four metallic rods arranged so as to leave a free path between them. Voltages are applied to these rods. For given voltages only ions with a certain mass-on-charge ratio travel down the central path between the rods before reaching the detector. All other ions are deflected. Voltages vary so as to scan the entire mass range.

In a high-resolution magnetic sector MS, ions are accelerated by a high voltage and pass through a series of ion optics, an electrostatic analyzer (ESA), and finally a magnet. By varying the strength of the magnet, the ions are separated according to their mass-on-charge ratio. They travel through a slit into a detector, which records a small atomic mass range at a given time. By varying the magnet and ESA settings, the entire mass range can be scanned within a relatively short time.

A TOF mass spectrometer permits the simultaneous detection of a full mass spectrum in approximately 30 μs, whereas quadrupole and high-resolution magnetic sector mass spectrometers are sequential analyzers. With TOF-MS, a pulsed electric field accelerates the ions to the

same kinetic energy with the velocity of the ions depending on their mass-on-charge ratio. The time it takes for the different ions to reach a detector is then measured, the lighter particles moving faster than the heavier ones.

To avoid ions colliding with other molecules, the mass spectrometer is kept in a vacuum. An interface insures the transfer of the ions from the plasma at atmospheric pressure to the mass spectrometer maintained in a low pressure environment. The difference of pressures between the plasma and the mass spectrometer creates a supersonic jet, and the ions are accelerated as they go through the interface. They are then focused by a series of lenses and mirrors before entering the mass spectrometer.

Either liquid or solid samples can be analyzed with ICP-MS. In the first case, a few milligrams of the material to analyze is dissolved with ultrapure concentrated acids. To improve the process, it is sometimes necessary to use a microwave digestion system, which is a device that heats (under pressure) the acid solutions. After dilution, by means of a peristatic pump, the acid solution containing the dissolved sample is aspirated through a nebulizer with high velocity argon, forming a fine mist. A spray chamber removes and drains the larger droplets and only the smallest ones reach the plasma.

Laser ablation (LA) is used for the direct introduction of solid samples in the ICP-MS. In a standard setting, the object to analyze is placed in a chamber without any specific preparation. The size of the chamber limits the size of the objects. The chamber is usually a cylinder with a diameter of 5–6 cm and a height of 5 cm. A CCD camera connected to a computer allows the visualization of the surface of the sample. The laser beam interacts with the surface of the objects, vaporizing a small quantity of material that is flushed by a gas carrier, which is generally argon or helium. The parameters of ablation depend on the material and on the instrumentation. The diameter of the laser beam ranges from about 50 to 100 μm. The trace left at the surface of the object by the laser is generally invisible to the naked eye. A pre-ablation is set up to clean the surface of the object in order to remove contamination and to avoid eventual corrosion, which affects the results of the analysis.

Quantitative Results

To obtain reliable quantitative results, the use of internal and external standardizations is imperative with ICP-MS or LA-ICP-MS. To improve the reproducibility of measurements, an internal standard is required to correct possible instrumental drifts or changes in the sample introduction system's efficiency. For solutions, the internal standard, an element absent in the sample, is spiked in each sample and standard solution. For solid samples, the internal standard has to be an element already present in the material since no addition is possible. The chosen element has to have a relatively high concentration in each sample so its measurement is as accurate as possible. In order to obtain absolute concentrations for the analyzed elements, the concentration of the internal standard has to be known. Its concentration is either measured with another analytical technique or calculated assuming that the sum of the concentrations of the measured elements, in weight percent, is 100% (Gratuze 1999).

Quantitative results are obtained by comparing the signal intensity measured for a given element in a sample to the signal intensity for the same element in a standard solution or a standard reference material (SRM) with certified concentrations. To prevent matrix effects, the compositions of the standards have to be as close as possible to those of the samples.

In an unknown sample, when using LA-ICP-MS, concentrations in weight percent of element or of oxide are calculated assuming that the sum of their concentration is equal to 100% (Gratuze 1999):

$$\%Y = \frac{\frac{I_Y}{I_{(Int\ Std)} * K_Y}}{\sum \frac{I_X}{I_{(IntStd)} * K_X}} \qquad \%Y_mO_n = \frac{\frac{I_Y \times \alpha_Y}{I_{(Int\ Std)} \times K_Y}}{\sum \frac{I_X \times \alpha_X}{I_{(IntStd)} \times K_X}}$$

I_y, I_x, and $I_{(Int\ Std)}$ are the signal intensities corrected from the blank measured for the internal standard (Int Std) and elements Y and X in the sample. α_y and α_x are the conversion factor from element to oxide for element Y and X. K_y and K_x

are the response coefficient factor for element Y and X, calculated as follows:

$$K_Y = \frac{I_{Ystd} \times [\text{Int Std}]_{std}}{I_{(\text{Int std})_{std}} \times [Y]_{std}}$$

I_{Ystd} and $I_{(\text{Int std})\ \text{std}}$ are the signal intensities corrected from the blank measured for the internal standard (Int Std) and elements Y in the SRM and $[Y]_{std}$ and $[Int\ Std]_{std}$ are the concentration of the internal standard and element Y in the SRM. This approach assumes that the oxidation state of each element is known and ignores the presence of elements such as sulfur or the presence of water.

Other factors affecting quantitative results are the presence of isobaric (two isotopes at the same mass) and polyatomic (oxide, argide, etc., at the same mass as an isotope of interest) interferences and laser-induced elemental fractionation causing the preferential ablation of some elements. Several strategies are available to avoid interferences such as, for example, choosing a non-interfered isotope or operating the mass spectrometer at a higher resolution to resolve two peaks with close masses. Some quadrupole ICP-MS are equipped with a collision/reaction cell where polyatomic species are eliminated through collision or reaction with gases such as helium, oxygen, ammonia, and so on. Fractionation will depend on the sample matrix but also on the laser wavelength, ablation parameters, and acquisition time.

Applications

Applications in the field of archaeology involving ICP-MS began being developed in the 1980s. However, it is only after LA attachments came into use, giving archaeologists a virtually nondestructive analytical tool, that the full potential of this analytical approach was explored for the study of ancient materials (Gratuze et al. 1993; Telouk 1993). One of the difficulties is that, if ICP-MS can measure bulk compositions for materials as heterogeneous as ceramics or soils, the microscopic sampling performed with a laser is only representative of the artifact providing it has a fairly homogeneous composition. Another difficulty regarding quantitative analysis with LA-ICP-MS is the need for matrix matched standard reference materials (SRM). Archaeological samples have compositions that can be extremely complex due to the use of non-refined raw materials. They contain a wide range of elements not always present in modern materials.

Natural and synthesized glasses are reasonably homogeneous materials, and several SRM containing a wide range of elements of interest for archaeological study are available prompting the rapid multiplication of LA-ICP-MS analysis of glass. Trace element compositions have been shown to be vital for distinguishing several primary glass production workshops (Dussubieux et al. 2009).

If LA-ICP-MS provides the best results with such a material as glass, metals are more challenging. Ancient gold was the first metal to be investigated extensively with LA-ICP-MS due to its value and its high potential for revealing aspects of ancient economies. By determining major and minor elements, gold fineness can be easily assessed. Determining trace elements can help in tracking changes in ore supplies (Guerra and Calligaro 2004). The presence of inclusions of platinum group elements in gold objects can give clues about the provenance of the metal, but also is a source of heterogeneities that can affect measurements with LA-ICP-MS. To overcome this challenge, elemental ratios rather than absolute concentrations are taking into account (Jett et al. 2007). Silver and iron-based artifacts have raised less interest, but several articles demonstrate the feasibility of determining their composition using LA-ICP-MS. Technical issues regarding iron (Devos et al. 2000) and silver (Sarah et al. 2007) artifacts were addressed using LA-ICP-MS, and authenticity verification for silver objects was performed (Devos et al. 1999). The development of a LA-ICP-MS protocol for ancient copper alloys is more recent. The presence of thick layer of corrosion at the surface of copper-based artifacts and the immiscibility of some elements, such as lead in copper, may affect LA-ICP-MS measurements. Performing a "cleaning" ablation with a larger diameter beam prior to the ablation undertaken for the measurement of the composition of the objects is usually sufficient to

reach the uncorroded metal (Dussubieux et al. 2008). A basic knowledge of metallurgy is necessary for an accurate data interpretation.

Ceramic study plays a central role in many archaeological projects, because of the ubiquity of this material. The elemental composition of ceramic samples may reveal the provenance of the artifacts when data about possible clay sources are available or at least indicate whether a unique source or a variety of sources were used for ceramic procurement at a given site. Instrumental Neutron Activation Analysis (INAA) was, for years, the analytical technique of choice to measure the composition of ceramics, because of the large number of elements it could determine and its good sensitivity. However, this method suffers from major inconveniences: it requires access to a nuclear reactor, it produces radioactive material as a byproduct, and artifacts are irremediably damaged or destroyed. In more and more instances, LA-ICP-MS is proposed as an alternative to INAA for ceramic analysis. The use of laser ablation for sampling instead of acid digestion to dissolve a small quantity of ceramic saves the long and tedious process of sample preparation but faces many challenges due to the heterogeneous nature of the material. In many cases, ceramic compositions as measured by INAA and LA-ICP-MS lead to similar groupings providing that only clay is targeted unless the temper is extremely fine-grained and indistinguishable from the clay. The composition of the ceramic is calculated from the average of the multiple measurements carried out on each sample after elimination of any "abnormal" measurements due to the ablation of temper grains or from any other heterogeneity in the ceramic fabric under the sample surface (Dussubieux et al. 2007; Vaughn et al. 2011). Any contribution from the temper that may subsist will appear in the composition causing a dilution effect of the clay composition that can be corrected using a dilution correction (Harbottle 1976; Mommsen 2007).

While glass, metals, and ceramic are now materials routinely analyzed using LA-ICP-MS, other materials need to be considered on a more case-by-case basis such as stones, soils, or biogenic materials. Speakman and Neff (2005) proposed a range of applications including the materials mentioned above as well as jade, chert, pigments, and human dental enamel. Since then, the list of materials investigated with LA-ICP-MS keeps getting longer and longer (Resano et al. 2010).

Current Debates and Future Directions

The use of laser ablation with ICP-MS in archaeology has permitted a range of applications that keeps expanding as the laser technology itself improves with the increasing availability of lasers with shorter wavelengths (213 nm, 193 nm) and, more recently, the use of femtosecond lasers. These lasers, with improved ablation characteristics, limit or eliminate fractionation problems encountered with some matrices (e.g., metals).

The size of the chamber of the laser ablation system commercially available limits the size of the objects that can be analyzed nondestructively. Rather than placing the objects into a cell, different experimental solutions were proposed to ablate directly the surface of a large object placed under an open ablation cell (Wagner and Jędral 2011). More recently, direct atmospheric sampling was tested successfully on some ancient artifacts eliminating some of the problems that may occur when attaching an open ablation cell on especially fragile objects (Kovacs et al. 2010).

As portable analytical methods are gaining more and more ground in the toolkits of the archaeologists, efforts are currently being made to design a portable laser ablation system for in situ sampling of artifacts that cannot be taken to a lab (Glaus et al. 2012).

If the laser itself is important, the way it is used for sampling can be modulated to the specific need of the artifact to be investigated and the questions to be addressed. Composite artifacts can be analyzed with LA-ICP-MS by targeting with the laser areas that look visibly distinct. However, in certain cases, when different compositions do not yield visual changes at the surface of the object

or when surface and core compositions are different, the standard sampling approach using single point or scan sampling will fail giving an accurate compositional picture of the object. The difficulty of mapping an artifact or portion of an artifact lies first in the large quantity of data generated that needs to be processed. A simplified calculation approach was developed for glass, and the results are displayed in a meaningful way using software specially designed for this purpose (Triglav et al. 2010). Depth profile analysis faces different challenges. One of them is fractionation that occurs for some elements after several minutes of ablations. A standardization procedure with calculation of the concentrations is used to offset the fractionation effects on the concentrations. Memory effects are limited by the design of small volume cells.

On the ICP-MS front, the future will certainly see more and more applications dealing with isotope analysis (Resano et al. 2010). Indeed, in many cases, information provided by elemental analysis is not sufficient to be able to provide any provenance hypothesis. The measurements of isotope ratios of elements, such as lead or strontium, have been successfully used in the past to source raw materials; however, it requires a labor and cost intensive sample preparation as well as high-resolution mass spectrometers. Some laboratories are exploring the use of LA-ICP-MS for isotope analysis as a nondestructive alternative for some applications that do not require the highest precision.

Conclusion

Over the past 20 years, new areas of research have been developed and explored in the field of archaeology, based on the trace element signature of artifacts and raw materials determined with ICP-MS. ICP-MS, when used in conjunction with laser ablation, combining minimally destructive sampling with high accuracy, good precision, and low detection limits, is an extremely attractive analytical method to archaeologists. Being a relatively low cost analytical method with a high sample throughput, large numbers of objects, up to several hundreds, can be studied. This permits a more comprehensive temporal and spatial sampling of a given type of artifact. The large bodies of data generated are also better tools to reveal patterns in connections with trade and exchange when examined using appropriate statistical treatments.

Industrial Archaeology

Marilyn Palmer
School of Archaeology and Ancient History, University of Leicester, Leicester, UK

Introduction

The earliest periods of human history are still defined by the archaeological evidence for fundamental changes in the materials from which people made objects and the increasingly refined methods they used to make them. The importance of conserving and studying the evidence for these changes is universally accepted as a legitimate archaeological activity. From the medieval period onward in Europe, innovations in the use of mechanical energy as well as extended commercial activity created the conditions toward the end of the eighteenth century for an equally fundamental change in the methods of manufacturing objects, resulting in an economic and social transformation sufficiently rapid and profound as to deserve the term "industrial revolution." This signified the beginning of a historical phenomenon that has affected an ever-greater part of the human population, the landscape, and even the climate of our planet and continues to the present day.

However, at least in the western hemisphere, it was not until the physical evidence for the innovations that triggered this change – water- and steam-powered machines, mills and factories, iron furnaces and pottery kilns, canals and railways, and the houses in which the workforce lived – came under threat in the middle of the twentieth century that much attention was paid to the need to study, record, and even conserve them. Unlike most pre-medieval industrial sites, much of the physical evidence was still above ground, although in many cases rusting away or becoming ruinous. As a result, industrial archaeology, as the discipline embracing such activity came to be called, was from the beginning as much about saving what was under threat as studying this material culture to further our understanding of the causes and consequences of industrialization. Obviously, the

two aspects come together: it is impossible to conserve and interpret industrial structures and objects unless they are understood through archaeological and historical study. Yet the popular and even the professional conception of industrial archaeology has tended to adopt its meaning as a movement to conserve the industrial past, which would be better termed "industrial heritage," rather than its meaning as the study of the ways people worked in the recent past. This emphasis on conservation and preservation of sites currently distinguishes industrial archaeology from both post-medieval and historical archaeology and had until the last decade of the twentieth century hindered its acceptance among professional archaeologists. On the other hand, industrial heritage preservation has always attracted a great deal of interest and support from the voluntary sector as well as public bodies with an interest in their tourist potential. However, the increase in archaeological work on brownfield sites as part of developer-funded archaeology has begun to redress this balance; in the first decade of the twenty-first century, roughly 30% of all professional archaeology done in the UK examined archaeological deposits that included material from the classic period of industrialization, and industrial archaeology is now widely recognized as a legitimate archaeological activity and not just a form of heritage conservation (Fig. 1).

Definition

Some early practitioners of industrial archaeology argued that the discipline was a thematic rather than a chronological one and could range from the prehistoric to the modern period (Raistrick 1972). However, the rapid decline of many traditional industries and the growing recognition of the historic value of textile mills, iron works, and transport networks have led to a general acceptance that industrial archaeology involves the systematic study of standing as well as subsurface structures of the classic period of industrialization from the early modern and modern periods, mainly the early eighteenth to the twentieth century. What characterizes this period is capital investment on a large scale in both buildings and equipment and the organization of the labor force to maximize production. It is with these developments that industrial archaeology is largely concerned, although it must be recognized that "industrialization" began earlier in some industries than others and that therefore an interpretation of a particular site or industry may need to go back to the sixteenth century or earlier. Equally, it is clear that the domestic or home-based method of production continued to coexist with large-scale factory-type production well into the nineteenth century, albeit with many changes in the lifestyle of the workforce (Barnwell et al. 2004).

Industrial archaeology is necessarily an interdisciplinary activity, requiring familiarity with normal archaeological techniques such as landscape surveying, artifact recognition, measured survey, and excavation. However, the discipline has its own needs and skills driven by the material

culture of industrialization. These include some knowledge of the technology and science of the period, an understanding of the contemporary documentary material available to augment archaeological fieldwork, and the ability to record standing industrial buildings and structures and to understand their function within what is often a sequence of industrial processes (Palmer and Neaverson 1998; Palmer et al. 2012).

Historical Background

Industrial archaeology as a discipline originated in the UK in the 1950s, after the postwar preoccupation with renewal had led to the destruction of much of the landscape associated with early industrialization. It is generally agreed that the term was first used in print in 1955 by Michael Rix, staff tutor in architectural history in the University of Birmingham's Department of Extramural Studies, where the surrounding Black Country was witnessing some of the worst of the devastation. Although the efforts to save industrial buildings and structures might more appropriately be termed "industrial heritage," Rix emphasized the importance of an archaeological approach to industrial sites: "the prime task of the industrial archaeologist at the moment is an archaeological one and that is in fieldwork." He also posed a challenge to the archaeological community: "industrial archaeology serves as a useful reminder to the whole archaeological world that the *terminus post quem* of archaeological research is not 55 BCE nor CE 410. The *terminus post quem* of archaeological research is today" (Rix 1967: 18). The cause was taken up by the Council for British Archaeology, which itself had been founded in 1944 in response to wartime devastation and had established its role as a forum for representing the views, ideas, and policies of British archaeology to the government, the media, and the public. The statutory bodies, however, failed to respond to the call to record and save industrial monuments, with the notable exception of Northern Ireland where a publically funded survey had been set up as early as 1956 (McCutcheon 1980). As a result, the early surveys of industrial monuments in the rest of Britain were undertaken largely by volunteers. Their records were collated by Dr. Angus Buchanan at the University of Bath from the mid-1960s, eventually being taken over as part of the National Monuments Record, and many published gazetteers of industrial sites by county followed (Buchanan 1972; Cossons 2000; Palmer 2019).

Similar inventory work on industrial sites followed in Europe, generally with more professional and less amateur involvement than in the UK. Although French historians had for a long time been interested in industrial history, little notice was taken of the industrial sites themselves until the 1970s, and it was not until 1983 that the *Inventaire Générale* began to include industrial sites with the foundation of an industrial heritage group within it, the *Cellule du Patrimoine Industriel*. A long-term project to create a national database of French industrial sites was initiated in 1986, and a similar database project was begun in the Netherlands where responsibility for the industrial heritage passed to the Netherlands Federation of Industrial Heritage, formed in 1984. In Belgium, various categories of industrial buildings were surveyed, particularly water mills and windmills, and a national survey published by Patrick Viaene in 1986. The Scandinavian countries have an important industrial heritage, particularly in mining of copper and iron (Fig. 2), which largely through the efforts of Marie Nisser were increasingly recognized as significant by their governments, while in Denmark, industrial sites, including those of the twentieth century, have been recorded by its National Culture Heritage Agency.

In areas of the world with a shorter written history than Europe, the discipline of historical archaeology was taken to embrace the study of industrial sites and artifacts. It was pointed out in *Australian Pioneer Technology*: *Sites and Relics* (Birmingham et al. 1979) that the use of the term "industrial archaeology" in Australia was inappropriate since the time span of British industrial archaeology embraced the whole of Australian history since European settlement. In the USA, too, many historical archaeologists did not see the need for a different term for the study of industrial sites, since again the majority of their work was

Industrial Archaeology, Fig. 2 Copper mining and smelting have dominated the Norwegian town of Røros since its foundation in the late seventeenth century. Below the slag heaps are the ramshackle wooden workers' houses with their grassed roofs, while the company town is dominated by the late eighteenth-century Baroque church. Mining continued in Røros well into the twentieth century, but the importance of the town's historic remains was carefully conserved and accorded World Heritage status in 1980

concerned with the post-1492 colonial era although generally dealing only with subsurface structures and buried artifacts. Nevertheless, surveys of engineering structures in the USA had been carried out since the 1930s by the Historic American Buildings Survey (HABS), set up as a means of providing work for unemployed architects during the Depression. A pioneering survey of New England textile mills was undertaken by HABS in 1967–1968 (Fig. 3). This was followed by the creation in 1969 of the Historical American Engineering Record (HAER) under the aegis of the National Park Service. The records of these two bodies are maintained by the Library of Congress in what is termed "preservation by documentation" and are among the most heavily used collection in its Prints and Photographic Division. In Australia, the Australian National Trust published lists of industrial sites from the 1960s and went on to conserve many of them at state level, notably the important mining landscapes of gold, copper, and silver at Moonta and Ballarat.
